Dear Colleagues,

As Co-chairs of the 2015 World Congress on Medical Physics and Biomedical Engineering, it is our great pleasure to welcome you to Toronto.

The World Congress is co-hosted by IUPESM (International Union for Physical and Engineering Sciences in Medicine), IOMP (International Organization for Medical Physics), IFMBE (International Federation for Medical and Biological Engineering), and here in Canada by COMP (Canadian Organization of Medical Physicists) and CMBES (Canadian Medical and Biological Engineering Society). These five organizations have collaborated to ensure that this Congress features exciting scientific sessions on a wide range of topics in medical physics and biomedical engineering, presented by scientists and engineers from around the world.

The Congress Organizing Committee and its sub-committees have worked hard to develop a rich and stimulating scientific program, with time set aside for mingling with colleagues and celebrating our successes. We are also proud of the range of plenary sessions, ancillary meetings and continuing education events being offered, along with an excellent range of exhibits. We encourage you to explore and participate in the various offerings of the congress. We also thank our congress planning partners, International Congress Services Ltd., whose people have worked tirelessly to ensure that this Congress is a rewarding and pleasurable experience for all.

We encourage you to reconnect with colleagues you may not have seen for a while, and to take the opportunity to meet new colleagues and form new connections around the world. Also, do take some time to explore our city. Here in Toronto, we are proud to be one of the most multicultural cities in the world, and of our rating as the safest large metropolitan area in North America. There are many exciting cultural sites nearby and a wonderful variety of restaurants serving many different cuisines, so don’t hesitate to explore our city and enjoy its warmth and diversity.

Thank you for attending the 2015 World Congress, and welcome to Toronto!

David Jaffray, PhD

Tony Easty, PhD, PEng, CCE
Welcome to the 2015 World Congress on Medical Physics and Biomedical Engineering

We have created a World Congress—Why? What possesses us to work for three years to create this triennial event? Are we crazy? What has compelled David and Tony to take a chunk of their lives and of those many, many other people who contributed on the Congress Organizing Committee and all of the other WC 2015 committees and donate it to a World Congress on Medical Physics and Biomedical Engineering? This is among the greatest non-deductible, charitable contributions of which I am aware! It must be pretty important to them and to us. Thank you David Jaffrey and thank you Tony Easty—I don’t know how many times you will hear this during the coming week, but I can assure you that it will not be enough times!

Anticipation for this World Congress has been building slowly since our last gathering in Beijing, but recently that anticipation has been crescendoing. We have collected an international snapshot of advances in medical physics and biomedical engineering. This is an excellent opportunity to share best practices and theories, strengthen and create new global relationships, mentor young engineers and physicists and begin new projects at home and abroad. Thank you all present for your support and assistance in making WC 2015 a success! We could not have done it without you.

The five themes of the World Congress are:

1) Global Health Challenges,
2) Evidence and Health Informatics,
3) Women in Biomedical Engineering and Medical Physics,
4) Urban Health and Future Earth, and
5) Next Generation Medicine.

These are broad themes that capture some of the most important issues we face today.

We have the privilege of celebrating the lives and work of several IUPESM, IFMBE and IOMP Award winners, who will be introduced at the Opening Ceremony and will each give us a “kort verslag” or precis of their work. We will have the additional pleasure of recognizing the achievements of early-career medical and biological engineers and medical physicists who have won one of several young investigator awards here in Toronto.

You, the people here, will have the opportunity to discuss the future of clinical engineering, medical physics and biomedical engineering. You have the chance to attend many special sessions within the 5 themes and 19 tracks of the World Congress. You can help shape policies for both developed and developing nations.

The delegates to the IUPESM General Assembly and the IOMP and IFMBE General Assemblies will be able to select their leaders for the immediate future; they will also select the location of the 2021 World Congress. Please delegates - vote intelligently and secure a good realization of our future.

Since I first read these words of T.S. Eliot in LITTLE GIDDING (No. 4 of ‘Four Quartets’) I have been strangely calmed by them; I thought I would share them with you as I wish you a successful WC 2015:

We shall not cease from exploration
And the end of all our exploring
Will be to arrive where we started
And know the place for the first time.

Best wishes,

Herbert F. Voigt, PhD
IUPESM President
Welcome to World Congress on Medical Physics & Biomedical Engineering 2015, Toronto, Canada

Kin-Yin Cheung, President of IOMP

On behalf of the International Organization for Medical Physics (IOMP), it is my great pleasure and honour extending my warmest welcome to all participants in this 13th World Congress on Medical Physics & Biomedical Engineering being held in the wonderful city of Toronto, Canada during June 6-12, 2015.

I wish to convey my gratitude to the Canadian Organization of Medical Physicists (COMP) and Canadian Medical and Biological Engineering Society (CMBES) for hosting this great event and to congratulate them for the huge success in this special occasion. The event provides a unique opportunity and a multi-disciplinary scientific platform for medical physicists, biomedical engineers, and other professionals from related fields from all over the world to exchange ideas and share their knowledge, experience, and research findings for the purpose of promoting human health through advances in science and technology in healthcare.

I would also like to congratulate the Congress Co-Chairs, Professor David Jaffray and Dr. Tony Easty, and their team members for putting up an outstanding congress with such an excellent scientific program. May I convey my appreciation to them for all their efforts and contributions in making this congress a most memorable one.

Last but not least, I wish all participants a very fruitful congress and an enjoyable stay in the beautiful city of Toronto.

Kin-Yin Cheung, PhD
President
Welcome to the World Congress on Medical Physics and Biomedical Engineering 2015!

Each and every World Congress on Medical Physics and Biomedical Engineering is a chance for delegates from numerous countries from all over the world to review their own achievements and to have a closer look into the future of medical physics and biomedical engineering: which are the hottest topics in research, what can be expected from research results and from development, which are the new emerging technologies and what impact may be expected from them in medicine and health care, what are the highest needs for current care givers, how to make the education in medical physics and biomedical engineering better and more efficient. The World Congress is a platform for medical physicists and biomedical engineers to build a common policy for further improvement of health care and for planning common action under the umbrella of the International Union for Physical and Engineering Sciences in Medicine (IUPESM).

International Federation of Medical and Biological Engineering (IFMBE) is proud to be a sponsor of the World Congress this June, in Toronto, Canada. Biomedical engineers from most of more than 60 IFMBE affiliated Biomedical Engineering Societies will gather to exchange their knowledge and experience between themselves and also with colleagues who have their primary interest in medical physics, medicine and other professions linked with biomedical engineering. Contacts made at previous World Congresses enabled building of international research team which were successful gaining project in the field and where collaboration lasted for a long time. The Federation makes the most of the World Congress to reward distinguished scientists in biomedical engineering who have devoted their research for many years to biomedical engineering but at the same line, rewards early stage scientists and young investigators. There is more that 50 years since the Federation was founded (in 1959) and from the first World Congress in 1982, so that a whole crosssection of careers in biomedical engineering can be identified and appropriately evaluated.

I sincerely hope that all delegates of the Congress will gain from the scientific sessions and also that you all will enjoy the social activities of and around the Congress and of the appealing city of Toronto!

Ratko Magjarević, PhD
President, IFMBE
June 7–12, 2015

**A Personal Message from the Premier**

On behalf of the Government of Ontario, I am delighted to extend warm greetings to everyone attending the IUPESM World Congress on Medical Physics and Biomedical Engineering in Toronto.

I would like to take this opportunity to commend the IUPESM for its commitment to supporting biomedical engineers and physicists in the ongoing advancement of these vital fields.

As Premier, I am proud that Ontario has the opportunity to host an event that facilitates fruitful discourse between clinicians, researchers, educators and practitioners with the noble aim to improve global health outcomes. With an impressive array of lectures, educational sessions and workshops, this conference is sure to both enlighten and inform.

I would also like to thank IUPESM for choosing our province to host this wonderful event. I am confident that all the delegates and guests will enjoy their time in Toronto, our vibrant and diverse capital city.

Please accept my best wishes for an informative and memorable congress.

*Kathleen Wynne*

Premier
Welcome / Bienvenue

On behalf of the Canadian Medical and Biological Engineering Society, I would like to welcome each of you to Toronto for the World Congress on Medical Physics and Biomedical Engineering.

The committee organizers and countless volunteers have worked hard to put forward a great program including an impressive line-up of educational courses.

I would like to extend my appreciation for the support of the Sponsors and Exhibitors who will be on hand Sunday evening through Thursday to market their latest products and services. Please spend some time at the Exhibit Hall to see what's new and improved.

Note that CMBES is celebrating its 50th anniversary this year. We have an amazing and rich history founded by innovators, scientists, and biomedical/clinical engineers, who uniquely served patients, the medical community, and Canadian Healthcare.

Please enjoy the learning and sharing with colleagues from the international community over the next few days and don't forget to join us for the Gala dinner on Wednesday night and the AGM on Thursday evening. I also hope you have a little bit of spare time to enjoy some of the sights around Toronto.

Au nom de la Société Canadienne de Génie Biomédical, j'aimerais souhaiter la bienvenue à chacun de vous à Toronto pour le Congrès Mondial sur la physique médicale et le génie biomédical.

Les organisateurs du comité et les innombrables bénévoles ont travaillé très fort pour mettre de l'avant un excellent programme qui inclut également un nombre impressionnant de cours de formation continue.

Je tiens à exprimer ma gratitude pour le soutien des commanditaires et des exposants qui seront sur place du dimanche soir au jeudi pour présenter leurs plus récents produits et services. N'oubliez pas, s'il vous plaît d'en profiter pour prendre quelques minutes pour aller au salon des exposants afin de découvrir les dernières nouveautés et améliorations.

Notez que le CMBES célébre son 50e anniversaire cette année. Nous avons une histoire étonnante et riche fondée par les innovateurs, les scientifiques et les ingénieurs cliniques et biomédicaux, qui ont concentré leurs efforts pour apporter des bénéfices pour la santé des patients, la communauté médicale et le système de santé canadien.

Je vous souhaite une bonne conférence et j'espère que vous profiterez de cette occasion d'apprendre et de partager avec les collègues de la communauté internationale au cours des prochains jours. N'oubliez pas de nous rejoindre pour le dîner de gala du mercredi soir et l'Assemblée Générale du jeudi soir. Enfin, j'espère aussi que vous trouverez un peu de temps libre pour profiter de certains des attrats touristiques de Toronto et sa région.

Sincerely,

Martin Poulin, M.Eng., P.Eng.
President, CMBES/SCGB
Dear Delegates of the 2015 World Congress on Medical Physics and Biomedical Engineering,

On behalf of the Canadian Organisation of Medical Physicists and the Medical Physics community in Canada, Welcome to Toronto!

The theme for this year’s World Congress is “Health * Technology * Humanity”. I believe this captures the spirit of this meeting, and explains why it is so important that Medical Physicists and Biomedical Engineers meet together, and on a world scale. Medical technology is increasingly central in patient care; we as Physicists and Engineers are uniquely trained and able to improve human health through technology. The World Congress is the most comprehensive medical technology meeting in the world; this year we are welcoming delegates from 89 countries from all corners of the world to come to Toronto and share our knowledge and ideas to help improve human health for everyone.

COMP is very pleased to be able to contribute to improving global health through our contributions to this meeting. The planning for this meeting has been underway in earnest for about 20 months now, and we are grateful for the many volunteers who have committed much time and effort to plan this meeting for you. COMP is also grateful to our partner organisation in this event, the Canadian Medical and Biological Engineering Society, for co-organising the event with us. I believe that both societies are benefited tremendously through the interactions and planning with our partners. We are also grateful to the World Organisations, the IUPESM, IOMP and IFMBE, for giving us the opportunity to plan the premier Medical Physics and Biological Engineering conference in the world. It has been a privilege to host this event, and we are proud to be able to bring it to you.

I would like to reserve my greatest thanks to you, the delegates attending this meeting. This meeting will offer a world class program of talks and education sessions, covering 19 different tracks that could not be possible without your contributions. Without your hard work, commitment and enthusiasm for medical technology, this meeting would not be possible.

Thank you for making the trip to Toronto, and enjoy the meeting!

Marco Carlone, PhD
President, COMP
HOSTS & COMMITTEES

HOSTS

International Union for Physical and Engineering Sciences in Medicine (IUPESM)

The IUPESM represents the combined efforts of more than 40,000 medical physicists and biomedical engineers working on the physical and engineering science of medicine. The principal objectives of IUPESM are: (a) to contribute to the advancement of physical and engineering science in medicine for the benefit and wellbeing of humanity; (b) to organize international cooperation and promote communication among those engaged in health-care science and technology; (c) to coordinate activities of mutual interest to engineering and physical science within the health care field, including international and regional scientific congresses, seminars, working groups, regional support programs and scientific and technical publications; (d) to represent the professional interests and views of engineers and physical scientists in the health-care community.

International Organization for Medical Physics (IOMP)

The IOMP represents over 18,000 medical physicists worldwide, 80 adhering national member organizations and 6 regional organizations. The mission of IOMP is to advance medical physics practice worldwide by disseminating scientific and technical information, fostering the educational and professional development of medical physicists, and promoting the highest quality medical services for patients.

International Federation of Medical and Biological Engineering (IFMBE)

IFMBE is primarily a federation of national and transnational organizations. These organizations represent national interests in medical and biological engineering. The objectives of the IFMBE are scientific, technological, literary, and educational. Within the field of medical, biological and clinical engineering IFMBE’s aims are to encourage research and the application of knowledge, and to disseminate information and promote collaboration.

Canadian Organization of Medical Physicists (COMP)

COMP is the main professional body for medical physicists practicing in Canada. The membership is composed of graduate students, professional physicists, scientists, and academics located at universities, hospitals, cancer centers, and government research facilities. Every member has an educational or professional background in physics or engineering as it applies to medicine. COMP’s vision is to be the recognized leader and primary resource for medical physics in Canada. COMP’s mission is to champion medical physicists’ efforts for patient care excellence through education, knowledge transfer, advocacy and partnerships.

Canadian Medical and Biological Engineering Society (CMBES)

CMBES is Canada’s principal society for engineering in medicine and biology. The Society’s aims are twofold: scientific and educational: directed toward the advancement of the theory and practice of medical device technology; and professional: directed toward the advancement of all individuals in Canada who are engaged in interdisciplinary work involving engineering, the life sciences and medicine.

CONGRESS VENUE

The IUPESM World Congress 2015 will take place in the South Building of the Metro Toronto Convention Centre. The Convention Centre is located in the heart of downtown Toronto. The South Building is accessible via Bremner Boulevard as well as from the North Building via Front Street.

Metro Toronto Convention Centre
South Building
222 Bremner Boulevard,
Toronto, Ontario, Canada M5V 3L9

Toronto, Ontario, Canada

One of Canada’s best kept secrets, Toronto is on par with New York City, San Francisco and Chicago when it comes to cultural attractions and urban sophistication.

The landmark CN Tower is the tallest freestanding structure in the world. Take the elevator to the top for a breathtaking view of the city, Lake Ontario and more. Stroll next door and experience Ripley’s Aquarium as you explore the wonders of the sea or catch a Blue Jays Baseball game at Rogers Centre or just walk around the massive engineering marvel. Check out the Royal Ontario Museum, the largest in Canada with its fascinating archaeology and natural history exhibits, and the Art Gallery of Ontario, with a fine collection of European and Canadian works. You won’t want to miss the electric shops and restaurants on Queen Street West or the elegant boutiques and fine restaurants in Yorkville.

And there’s more: harbour front is a complex of unique shops and restaurants right on beautiful Lake Ontario. From harbour front you can hop on a ferry to the Toronto Islands for a picnic and outdoor recreation such as beach volleyball.

Explore the area and take a day trip to another wonder of the world and experience Niagara Falls or take a break right next door and experience Ontario’s wine country. Toronto and the surrounding areas are a great family destination and most attractions are child-friendly. The city itself is clean, safe and easy to explore either on foot or by public transportation.
ADOPT A DELEGATE

The IUPESM 2015 World Congress is proud to support the ‘Adopt a Delegate/Student’ initiative, giving prospective delegates from a developed world setting the opportunity to adopt or part finance the registration and accommodation costs of a peer from an emerging economy.

▶ We would like to thank the following people for their consideration and support:

Herbert F. Voigt
David Rogers
David Jaffray
Modus Medical Devices Inc.
Murray Rice
Grace Zeng
William Gentles
Raymond Wu
Ichiro Sakuma
David Spencer
Vincent Lam
Joyce Shen
Tony Easty

SCIENCE FAIR

YOUTH OUTREACH

Winners of a local science fair have been invited to participate in the IUPESM 2015 Youth Outreach Program. 26 youths between the ages of 15–18 will present their 18 Science Fair projects on Wednesday, June 10.

They will start their day by listening to the Key Note Session by Gordon MCBean and Mary Gospodarowicz, followed by attending the session on “What is a medical physicist? What is a biomedical engineer?” After, they are taken on a guided tour of selected posters and the exhibit floor by a Professor. After lunch, their day concludes by presenting their Science Fair projects in the Exhibit Hall, interacting with congress delegates.

DOWNLOAD THE MOBILE APP:

Abstracts Online/ Personal Itinerary Builder

Attendees are invited to utilize the World Congress 2015 App, which is available for download on the Congress Website at WC2015.org

This app allows you to view abstracts, presenters, the program schedule and sessions, selecting abstracts and sessions of interest to build your own personal itinerary builder.
Flat Albert is a flat version of very well known Albert Einstein.

We encouraged you to take a picture of Flat Albert in an interesting place and post it to our Facebook and Twitter pages #wc2015yyz.

Here are some of our favourites:
Registration Counter Hours

Registration is located on Level 600, South Building of Metro Toronto Convention Centre.

Sunday, June 7  11:00 – 20:00
Monday, June 8  07:00 – 17:30
Tuesday, June 9  07:00 – 17:30
Wednesday, June 10  07:00 – 17:30
Thursday, June 11  07:00 – 17:30
Friday, June 12  07:00 – 13:00

The Toronto Information Desk is located in the Registration area on Level 600, South Building of Metro Toronto Convention Centre. Staff will provide local information and assist with:

- Ground Transportation
- Airport Transfers
- Sightseeing Tours
- Pre- and Post Tours
- Restaurant recommendations and booking
- Local PA and Personal Concierge Services

Delegate Help Desk

Delegate Help Desk is located on Level 600, South Building of Metro Toronto Convention Centre.

Delegate Bag Booth

Delegate Help Desk is located on level 600, South Building of Metro Toronto Convention Centre

Sunday, June 7  11:00 – 20:00
Monday, June 8  07:00 – 17:30
Tuesday, June 9  07:00 – 17:30

Delegate Bags include:

- Invitation Flyers for Industry Supported Symposia
- Additional Promotional Flyers from Sponsors and Exhibitors

Name Badges

Delegates and guests are requested to wear their name badge at all times in order to participate in the Scientific Sessions, Social Events and Exhibition.

Lost Badge/Name Changes:
A 50 CAD fee applies for any reprints due to onsite name changes or lost badges.

Registration Materials

Registration Materials include:

- Name Badge
- Delegate Bag Voucher
  (not included in Accompanying Person Registration)
- Onsite Program Book Voucher

Badge Color Identification

Delegate – Blue
- Access to all Scientific Program & Continuing Education Sessions (except any specially ticketed sessions)
- Access to Exhibit Hall
- Congress Bag
- Onsite Program and Congress Handouts
- Welcome Reception
- Networking Breaks
- Discounted Gala Dinner Ticket

Single Day – Red
- Access to all Scientific Program & Continuing Education Sessions (except any specially ticketed sessions) on day of attendance
- Access to Exhibit Hall on day of attendance
- Congress Bag
- Onsite Program and Congress Handouts
- Networking Breaks on day of attendance

Exhibitor – Green
- Access to Exhibit Hall
- Onsite Program and Congress Handouts
- Welcome Reception
- Networking Breaks
- Option to Purchase Gala Dinner Tickets

Accompanying Person - Yellow
- Access to Exhibit Hall
- Welcome Reception
- Networking Breaks
- Discounted Gala Dinner Ticket Rate

LEAD RETRIEVAL
By allowing to have your badge scanned, you are indicating your consent to receive e-mail marketing.

If you require assistance or any information regarding the Congress, please see the staff at the Delegate Information Counter located in the registration area, on Level 600, South Building of Metro Toronto Convention Centre.
Speaker Ready Room

All invited speakers as well as oral abstract presenters are required to report to the Speaker Ready Room at least 24 hours prior to their scheduled presentation in order to upload their presentation slides or to check their previously uploaded slides. Computers are available to preview and upload presentations. Presenters should make sure all fonts appear as expected. No file submissions will be accepted in the session rooms.

The Speaker Ready Room is located in Room 705 on Level 700.

Invited Speakers and Oral / Abstract Presenters

All speakers are asked to be in the session room at least 10 minutes prior to the start of their session.

Poster Presenters

All Poster Presentations/Boards are located in Hall E on Level 800, South Building of Metro Toronto Convention Centre.

Each Poster Board will be shared by two posters on each side. The Poster Boards are identified with Poster Numbers that correspond with the pre-assigned Poster Numbers for each poster presentation. The Poster Numbers are also published in this program book and in the Online Abstract Book.

Poster set up time:
- Sunday, June 7 15:00 – 17:45
- Poster take down:
  - Thursday, June 11 17:00 – 19:00
  (any posters not removed by 19:00 will be discarded by management)

Poster Sessions

Posters will be displayed at all times during the Exhibit Opening Hours each day starting Sunday June 7. Presenters are asked to stand by their poster during the following times to informally answer questions from Congress delegates:

- **Morning & afternoon Networking Breaks:**
  - 10:00 – 10:30 AND 16:30 – 17:00 Monday, June 8 to Thursday, June 11.
- **During the Welcome Reception:**
  - 18:00 – 20:00 on Sunday, June 7.
Abstracts
All accepted and confirmed abstracts are published in the IUPESM World Congress Onsite Program and Abstract Book. This will be available on the Congress website.

All Full Papers accepted by the World Congress will be published by Springer in the IFMBE Proceedings 2015.

Delegate Lounges
The delegate lounges are located in the Exhibit Hall, see floorplan page 35.

Internet Café
The internet café is located in the Exhibit Hall.

Wireless Internet
Wireless internet is available in the public areas of the venue but not the meeting rooms or the Exhibit Hall.

Charging Station & Lounge
The charging station & lounge is located in the Exhibit Hall.

ELEKTA

Networking Breaks
Networking Breaks (hot beverages and snacks) are served on Level 700 at the following times:

- Monday, June 8: 10:00 – 10:30 and 16:30 – 17:00
- Tuesday, June 9: 10:00 – 10:30 and 16:30 – 17:00
- Wednesday, June 10: 10:00 – 10:30 and 16:30 – 17:00
- Thursday, June 11: 10:00 – 10:30
- Friday, June 12: 10:00 – 10:30

Lost and Found
Lost and found items should be returned/claimed at the registration desk.

Lunch
Lunch will not be provided by the Congress. However, there are plenty of restaurant choices in the area. A café, a convenience store and vending machines are all located within the Centre and there are also numerous restaurant options within a few minutes walk of the Convention Centre:

- SOCO Kitchen + Bar
  Located within the Delta Hotel offers laid back style of eating, with the opportunity to look over Bremner Street on their patio.
- Pita & Grill
  For a lighter meal head to Pita & Grill for a grab and go option.
- 360 Restaurant
  Upmarket Dining with sky high view in the world famous CN Tower.

CAMPEP Accrediation

For Medical Physicists:
The IUPESM 2015 World Congress Continuing Education Program is CAMPEP Accredited for up to 82 MPCEC credits. If you will be applying to CAMPEP for your MPCEC credits following the Congress and have not already paid the $11(CAD) CAMPEP fee then you will be able to pay this fee at the registration desk during registration hours. After the Congress you will be contacted by CAMPEP regarding Accreditation.

For Biomedical Engineers:
The IUPESM 2015 World Congress Continuing Education Program can be used for points towards Clinical Engineering Certification Renewal.
SOCIAL EVENTS

Be sure to join us for these events during the week:

- **Welcome Reception**
  SUPPORTED BY ELEKTA
  Sunday, June 7, 2015  18:00 – 20:00  Exhibit Hall E
  Enjoy some light hors d’oeuvres and a beverage, along with a subdued jazz trio, as you connect with exhibitors. This is your opportunity to network and connect with industry colleagues.

- **Opening Ceremony & President’s Welcome Address**
  Monday, June 8, 2015  10:30 – 12:00  Exhibit Hall F/G
  Your opening ceremony and president’s welcome address will be greeted by Canadian inspired entertainment, followed by the formalities of any President’s Welcome Address. You will hear all about what you can expect to experience throughout the congress and Toronto as your host city!

- **Gala Dinner**
  Wednesday, June 10, 2015  19:00 – 23:00  Exhibit Hall F/G
  After a busy week at the congress, tonight you will enjoy a delicious meal with fellow colleagues and new friends. Roaming entertainment will emerge throughout the evening and an upbeat band will perform top hits after dinner so you can show off your dancing moves.

- **Closing Ceremony & Awards Presentation**
  Friday, June 12, 2015  15:00 – 16:00  Exhibit Hall F/G
  Final remarks from the President, the organizing committees and your incoming officers will be announced here! Be sure to attend to hear where the next congress location will take place!
SOCIAL TOURS

Explore the area and take a day trip to experience one of the world wonders Niagara Falls or take the half day, fun and informative Toronto City Tour.

Niagara Falls Tour

The premium full-day tour of the Falls starts with your hotel pickup in the morning. On our first stop we’ll have time to explore Niagara-on-the-Lake.

www.niagarafallstourism.com/about/niagara-on-the-lake/

“NOTL” Niagara-on-the-Lake is a picturesque town just a few minutes drive outside of Niagara Falls. You’ll enjoy 40 minutes taking pictures and exploring some of the unique shops. Before you actually reach the Falls, we’ll also see the Floral Clock, Niagara River and whirl pool, Sir Adam Beck Power Station, Queenston Heights, and the Spanish Aero Car. During the day, we will make a stop at one of Niagara Falls’ famous wineries. There you will have an opportunity to sample wine before continuing our Niagara Falls adventure. The tour is structured to give you 2-3 hours of free time at the Falls. This gives you plenty of time to add in additional activities you want to do, plus stop for lunch, which is on your own time and budget. Recant the day’s memories on the bus ride back until you’re dropped back at your hotel doorstep.

Toronto City Tour

The half day, fun and informative Toronto City Tour will transport you to some of the city’s most popular sights as you relax aboard our new air-conditioned bus. We will show you over 17 attractions. Our stops include the St. Lawrence Market where you can buy lunch and a stroll through the pedestrian friendly Distillery District.

Shopping Tour

www.premiumoutlets.com/outlets/outlet.asp?id=109

Toronto Premium Outlets features a high end collection of the finest brands for you, your family and your home. Our Tour bus will pick you up from your hotel lobby between and take you the Outlets just 45 minutes outside of Toronto. Once we arrive you will receive a VIP Coupon book plus a special gift just for you from Toronto Premium Outlets management team.

Please go to our website for more details or to book a tour: wc2015.org/events-tours/pre-post-tours/

Accuray | Booth # 3104

Accuray Incorporated is a radiation oncology company that develops, manufactures and sells precise, innovative tumor treatment solutions that set the standard of care with the aim of helping patients live longer, better lives. The company’s leading-edge technologies deliver the full range of radiation therapy and radiosurgery treatments.

American Association of Physicists in Medicine (AAPM) | Booth # 1212

The mission of AAPM, a professional organization of 8,400+ members, is to advance the science, education and professional practice of medical physics. Visit booth #1212 for information on AAPM programs, to see a demonstration of the Virtual Library and to pick up complimentary copies of the Medical Physics journal.

ANDA Medical | Booth # 3604

ANDA Medical provides new and refurbished medical equipment to the global community. By locating medical products from the finest health facilities around the world, we maintain strong relationships with hospitals, medical suppliers, and OEMs. With consistent access to high-quality medical equipment we provide our customers with products at a fraction of the cost. This is our top priority.

ArjoHuntleigh Canada Inc. | Booth # 3213

A medical device company offering innovative solutions in Patient Handling, Therapeutic Surfaces, Medical Beds, Hygiene and Disinfection. ArjoHuntleigh offers programs to ensure facilities meet their needs while providing safe and efficient care.

Bayer Healthcare | Booth # 3503

Bayer’s Radimetrics™ Enterprise Platform is an integrated radiation dose and contrast dose* management solution. Platform tools can help customers drive compliance, efficiency and reproducible quality. Customizable dashboards facilitate enterprise-wide analytics and protocol management. With industry-leading repair capabilities, quality, and customer care, Multi Vendor Service provides the best value in third-party service.

*Requires Medrad® Stellant® CT Injection System/Certegra® Workstation

Best Theratronics | Booth # 3303

Best Theratronics Ltd. is a Canadian component of TeamBest™. We manufacture external beam therapy units (Equinox®, GammaBeam® 100-80, and the new GammaBeam® 500 Total Body Irradiator), blood and research irradiators (Gammacell® 1000 & 3000, Raycell® Mk2, Gammacell® 40E, GammaBeam® X200), and variable energy cyclotrons for radioisotope production and research.

Biomedical Engineering Society (BMES) | Booth # 2709TT

The Mission of the BMES is to build and support the biomedical engineering community, locally, nationally and internationally, with activities designed to communicate recent advances, discoveries, and inventions; promote education and professional development; and integrate the perspectives of the academic, medical, governmental, and business sectors.
**BRACCO® IMAGING Canada | Booth # 2301**

BRACCO® IMAGING Canada, world leader in medical imaging presents the latest contrast injection technologies in Radiology and Cardiac CathLab with ACISTCV™, CTExpress3D™ syringeless injector, and EmpowerCTA+™, with Nexo™ Contrast management and NexoDose™ Radiation Dose softwares. BIC distributes Invivo Corporation technologies (MR compatible patient monitoring, DynaCAD Breast and Prostate, UroNav fusion biopsy system, etc).

**Canadian Organization of Medical Physicists | Booth # 1115**

The Canadian Organization of Medical Physicists is the professional body for medical physicists in Canada. The membership is composed of physicists, scientists and academicians located at universities, hospitals, cancer centres and government research facilities as well as graduate students and post-doctoral fellows. Members have an educational or professional background in physics or engineering as it applies to medicine.

**Brainlab Technology | Booth # 1102**

Brainlab technology powers treatments in radiosurgery as well as numerous surgical fields including neurosurgery, orthopedic, ENT, CMF, spine and trauma. Founded in Munich in 1989, Brainlab has over 8,900 systems installed in about 100 countries.

**CareFusion | Booth # 2202**

At CareFusion, we serve the healthcare industry with products and services that support infection prevention, medication management, operating room efficiency, respiratory care and healthcare analytics products and services. As of March 2015, CareFusion has joined BD to become one of the largest global leaders in the medical technology industry.

**Canadian Medical and Biological Engineering Society | Booth # 2305**

The Canadian Medical and Biological Engineering Society is Canada’s principal society for engineering in medicine and biology. The Society’s mission is to advance and promote the theory and practice of engineering sciences and technology to medicine and biology, serving as a forum for information exchange between healthcare professionals, scientists, and the general public.

Please stop by the CMBES booth # 2513 to find out more about our role, programs, networking opportunities and the 2016 Congress in May, 2016 in Calgary, Alberta.

**Carleton University | Booth # 3406**

Carleton University, located in Canada’s beautiful capital city Ottawa, offers an MASc in biomedical engineering, and MSc and PhD Physics with specialization in medical physics (the PhD is CAMPEP accredited). Our programs are networked with world-class clinical facilities and national laboratories making Carleton a stimulating academic and research environment.

Carleton University, located in Canada’s beautiful capital city Ottawa, offers an MASc in biomedical engineering, and MSc and PhD Physics with specialization in medical physics (the PhD is CAMPEP accredited). Our programs are networked with world-class clinical facilities and national laboratories making Carleton a stimulating academic and research environment. carleton.ca

**Canadian Nuclear Safety Commission | Booth # 1228**

The Canadian Nuclear Safety Commission, Canada’s independent nuclear regulator, regulates the use of nuclear energy and materials to protect health, safety, security and the environment and to implement Canada’s international commitments on the peaceful use of nuclear energy; and to disseminate objective scientific, technical and regulatory information to the public.

**CDR Systems | Booth # 1127**

A global company CDR Systems offers proven next generation Frameless SRS, SRT, IMRT, IGRT, SBRT, Breast, Pelvis and H&N precision patient positioning and Immobilization products used by leading organizations worldwide. See why at our booth or email to arrange a demo. You can also keep in touch with the latest advancements in patient immobilization at: twitter.com/CDRSys and online www.cdrsyst.ca
CIMTEC builds and tests clinical prototypes in the broad areas of 3D visualization, image analysis and mechatronics design with specific expertise in image-guided interventions and digital pathology. Through technology development, business advice, and clinical testing, CIMTEC helps researchers, startups and small to medium-sized companies commercialize their medical imaging innovations.

CIRS is recognized worldwide for tissue simulation technology and is the leader in the manufacture of phantoms and simulators for radiation therapy QA and dosimetry, diagnostic imaging and quality assurance as well as training and demonstration phantoms for CT, mammography, ultrasound, MRI, radiation therapy, fluoroscopy, radiography and emerging modalities.

Covidien is a leading global healthcare products company that creates innovative medical solutions for better patient outcomes and delivers value through clinical leadership and excellence. Please visit www.covidien.com to learn more about our business.

CRC Press/Taylor and Francis is a leading international publisher of references, textbooks and professional handbooks in medical physics and biomedical engineering. Visit our booth to browse and enter to receive special prizes and discounts on new and bestselling titles. Editors Francesca McGowan (francesca.mcgowan@tandf.co.uk) and Michael Slaughter (Michael.Slaughter@taylorandfrancis.com) will be available to discuss new project ideas.

The Accelerated Education Program is putting innovation to work through education dedicated to promoting essential aspects of clinical care. Learning environments are engaging, creative and interactive, putting the focus on interprofessional activities that enhance team work. The goal of AEP is to deliver relevant, excellent programming for all radiation medicine professionals.

As an international leader in medical and safety technology, Dräger develops innovative equipment and solutions that people the world over trust. No matter where Dräger products are used, it’s always about life. Whether for use in the OR, ICU or Neonatal Care, Dräger products protect, support and save lives.

For over 65 years, Dunlee has remained at the forefront of medical imaging as an international leader in research, design, and manufacturing of high-performance replacement tubes for CT and general radiography. We also offer Technical Webinars and the Dunlee App, which features the Dunlee Academy, a virtual tube installation guide.

ECRI Institute is an independent nonprofit with more than 40 years of experience researching the best approaches to improving patient care. Our unbiased, evidence-based research, information, and advice help you address patient safety, quality and risk management challenges, procure cost-effective technology, and align capital investments with strategic technology needs.
Elekta | Booth # 1202

Elekta is a human care company pioneering significant innovations and clinical solutions for treating cancer and brain disorders. The company develops sophisticated, state-of-the-art tools and treatment planning systems for radiation therapy, radiosurgery and brachytherapy, as well as workflow enhancing software systems across the spectrum of cancer care.

Engineering World Health | Booth # 2713TT

Engineering World Health works with students and the BME community to improve healthcare delivery in developing world hospitals. We build local capacity to maintain medical equipment, make repairs, and develop low-cost technologies. Visit us to learn about our Summer Institute and making a lasting impact on developing world health care!

Fibertech | Booth # 2503

Fibertech continues to be the number #1 hospital equipment service facility in Canada. Specializing in repair of flexible and rigid endoscopes, rigid instrumentation, power tools and phaco hand pieces. Training and education programs provide a complete experience for our customer.

Fluke Biomedical / Unfors RaySafe | Booth # 3112

Together Fluke Biomedical and Unfors RaySafe strive to improve the quality of global health, one measurement at a time. We provide most reliable quality assurance solutions to make medical equipment safer to use. We serve biomedical engineers, quality-assurance technicians, medical physicists, oncologists, and radiation-safety professionals. For more information, visit www.flukebiomedical.com.

Fluke Biomedical / Unfors RaySafe | Booth # 3112

Fluke Biomedical is a company dedicated to selling high quality healthcare care products, and services to Radiation Oncology, Nuclear and Radiological imaging centers throughout Canada. With over 35 years of experience in the Canadian health care industry we have developed a reputation of providing outstanding customer service throughout the industry.

IBA | Booth # 1331

IBA is a global medical technology company focused on bringing integrated and innovative solutions for the diagnosis and treatment of cancer. The Company is the worldwide technology leader in the field of proton therapy. IBA also has a radiation dosimetry business and develops particle accelerators for the medical world and industry.
IEEE Engineering in Medicine and Biology Society | Booth # 2104

IEEE Engineering in Medicine and Biology Society is the world’s largest society of biomedical engineers. We provide access to people, practices, information, ideas and opinions shaping one of the fastest growing, technical fields. EMBS focuses on development and application of engineering concepts/methods to provide solutions to medical and healthcare problems.

Institution of Engineering and Technology | Booth # 2715TT

The IET journals portfolio offers high quality research in a number of topic areas including medical and biomedical research. Healthcare Technology Letters, IET Image Processing, IET Nanobiotechnology and IET Systems Biology are all key journals in this fast-paced field and considered an invaluable source for researchers and practitioners. Find out more at www.ietdl.org/journals.

International Federation for Medical and Biological Engineering (IFMBE) | Booth # 2309

The International Federation for Medical and Biological Engineering (IFMBE) is primarily a federation of national and transnational societies. These professional organizations represent interests in medical and biological engineering. The IFMBE is also a Non-Governmental Organization (NGO) for the United Nations and the World Health Organization (WHO), where we are uniquely positioned to influence the delivery of health care to the world through Biomedical and Clinical Engineering.

International Organization for Medical Physics (IOMP) | Booth # 1119

International Organization for Medical Physics (IOMP) represents over 18,000 medical physicists worldwide and 80 national member organisations.

The mission of IOMP is to advance medical physics practice worldwide by disseminating scientific and technical information, fostering the educational and professional development of medical physicists, and promoting the highest quality medical services for patients.

International Union for Physical and Engineering Sciences in Medicine (IUPESM) | Booth # 3214

IUPESM is a non-profit scientific NGO. The founding constituent organizations are IFMBE and IOMP. The objective is to contribute to the advancement of physical and engineering science in medicine for the well-being of humanity. IUPESM is the custodian of the triennial World Congress for Medical Physics and Biomedical Engineering.

IOP Publishing | Booth # 1103

IOP Publishing (ioppublishing.org) provides a range of journals, books, websites, magazines, congress proceedings and services through which leading-edge scientific research is distributed worldwide. Visit our stand to find out more about IOP Biosciences - our journals publishing in a number of fields, including medical physics, biomedical engineering and biophysics.

IPEM | Booth # 3606

Institute of Physics and Engineering in Medicine (IPEM) is dedicated to bringing together physical science, engineering and clinical professionals in academia, and healthcare to share knowledge, advance science/technology and inform/educate the public with the purpose of improving the understanding, and treatment of disease and management of patients.

iRT Systems | Booth # 1124

iRT is a new company founded in 2013 to introduce innovative new products into the radiation therapy market with the goal to improve patient safety and the overall quality of treatment.

Our first project is the development and certification of the Integral Quality Monitor (IQM) System, a revolutionary new device for real-time quality assurance.

LAP Laser | Booth # 1214

LAP of America Laser Applications, L.L.C has been delivering state of the art patient alignment laser systems for radiation therapy, nuclear medicine, and diagnostic radiology since 1997. Building on a strong tradition of excellence in the medical industry LAP has become the world leader in patient alignment laser systems.
MAQUET-DYNAMED

Swedish Group of companies GETINGE AB. The MAQUET brand represents the Medical Systems Business area and together with two other Business Areas ARJO Extended Care and GETINGE Infection Control, the entire GETINGE group of companies focuses on forward-looking medical technology.

ACMIT | Booth # 3203, 3206

ACMIT is a translational research center focused on technology for minimally invasive surgery that combines multidisciplinary know-how with that of international experts. The organizational structure of ACMIT reflects the quest for scientific excellence and successful technology development. ACMIT’s goal is to bring developments to their real use in clinical context within reasonable time.

CTMH | Booth # 3203, 3206

CTMH is collaboration between Karolinska Institutet, Royal Institute of Technology and Stockholm County Council to help develop the region as a world-class medical technology center. CTMH creates venues and activities that stimulate and develop exchanges between industry, academia and health care in the boundaries between technology, health, research and application.

Hong Kong Science & Technology Parks Corporation (HKSTP) | Booth # 3203, 3206

HKSTP is a statutory body dedicated to building a vibrant innovation and technology ecosystem to connect stakeholders, nurture technology talents, facilitate collaboration, and catalyse innovations to deliver social and economic benefits to Hong Kong and the region.

Institute of Biomedical Engineering | Booth # 3203, 3206

The Institute of Biomedical Engineering is a leading university-based deliverer of medtech R&D and innovation. The IBME brings together businesses, clinicians and academics to establish the technical feasibility, clinical desirability and commercial viability of cutting edge medical technology. We’re pioneering this engagement through both our MedTech Accelerator Programme and our PhD training scheme.

Medical Valley EMN | Booth # 3203, 3206

The Medical Valley EMN (e.V.) association assumes key tasks in the medical technology cluster and supports all members with comprehensive services. The association facilitates knowledge exchange, promotes the cluster internationally, and supports start-up companies. The overall goal is to develop the EMN area into a model region for optimal healthcare.

Morgridge Institute for Research | Booth # 3203, 3206

The Morgridge Institute for Research is a private, nonprofit biomedical research institute in Madison, Wis., affiliated with the University of Wisconsin–Madison. The institute works to improve human health by conducting, enabling and translating interdisciplinary biomedical research. Current research includes regenerative biology, virology, medical engineering and core computational technology.

Ontario Brain Institute | Booth # 3203, 3206

The Ontario Brain Institute is a provincially-funded, not-for-profit research centre seeking to maximize the impact of neuroscience and establish Ontario as a world leader in brain research, commercialization and care. We create partnerships between researchers, clinicians, industry, patients, and their advocates to foster discovery and deliver innovative products and service.
Sunnybrook Research Institute | Booth # 3203, 3206

Sunnybrook Research Institute (SRI) is the research enterprise of Sunnybrook Health Sciences Centre and is affiliated with the University of Toronto. Scientists at SRI strive to understand and prevent disease, and to develop treatments that enhance and extend life. They are renowned for excellence in the biological, physical and evaluative clinical sciences.

Techna | Booth # 3203, 3206

Techna is an institute of University Health Network, in collaboration with the University of Toronto, focused on the accelerated development and exploitation of technology for improved health. Techna is designed to shorten the time interval from technology discovery to application through a continuum of clinically driven innovation, technology & process development.

Thunder Bay Regional Research Institute (TBRRI) | Booth # 3203, 3206

Established in 2007 as Canada’s newest molecular imaging and advanced diagnostics research institute, TBRRI is now the research arm of the Thunder Bay Regional Health Sciences Centre. Currently Scientists, Physician Researchers and Clinicians are engaged in research which contributes to innovative treatments and improved diagnostic tools.

MedView Technologies | Booth # 2213

MedView was founded in 2013 to commercialize a highly innovative & proprietary technology based on Spatially Resolved Difusive Reflectance Spectroscopy, with potential applications in the medical diagnostics, pharmaceutical manufacturing, and food/material inspection fields. We are currently developing a vein detection medical device, with potential market size of up to $4B.

MIM Software Inc. | Booth # 2205

MIM Software Inc. provides practical imaging solutions in the fields of radiation oncology, radiology, nuclear medicine, urology, neuroimaging, and cardiac imaging. MIM offers solutions for computer workstations, as well as mobile and cloud-based platforms. MIM products are sold globally to imaging centers, hospitals, specialty clinics, research organizations, and pharmaceutical companies.

Mobius Medical Systems | Booth # 1323

Mobius Medical Systems provides the radiation oncology community with innovative software to streamline quality assurance. Mobius3D and MobiusFX are the first solutions for full 3D verification of both patient plan and delivery. Reclaim your nights and weekends! MobiusFX provides comprehensive patient specific QA in as little as one minute.

Modus Medical Devices Inc. | Booth # 1309

For 15 years, QUASAR™ has inspired physicists worldwide to seek the highest quality assurance standards in the field of medical imaging and radiotherapy. With 3,000 phantoms in over 1,800 treatment centres, Modus products are built to provide you with confidence that every patient is receiving the best possible treatment.

NELCO | Booth # 1205

NELCO is the worldwide leader in the design, manufacturing and construction of radiation shielding products and facilities for radiation therapy and diagnostic imaging. NELCO’s 80 year dedication to customer service, quality, and innovative products has resulted in over 4000 radiation therapy doors installed worldwide and over 5000 customers.

Olympus Canada Inc. | Booth # 2112

Olympus develops leading edge technology for healthcare professionals that help improve outcomes and enhance quality of life for patients. Visit us at Booth #2112 in the exhibit hall or on-line at www.olympuscanada.com
ImSimQA software is a complete toolkit for performing QA on Deformable Image Registration algorithms. OnQ RTS is an automated clinical system for performing Adaptive Planning functions including Deformable Image Registration. Add function without adding process to your department. Canadian distributors of MacroMedics immobilization and patient positioning devices.

Orfit Industries America | Booth # 1211

Orfit supplies High Precision Immobilization Systems including Adult / Pediatric Head/Neck systems using Frameless full and open face masks. MammoRx Breast Boards, SBRT Systems, Prone Breast Solutions, Extremities, Pelvis/Abdomen, Proton and MR Compatible systems are available.

Precision, reproducibility, ease of use, high patient comfort are hallmarks of the systems.

Pacific Medical LLC | Booth # 2106

Pacific Medical LLC specializes with providing PARTS and REPAIR SERVICES for Patient Monitors, Modules, Telemetry, Infusion Pumps, Suction Regulators, Fetal Transducers, SpO2/ECG/TEMP/NIBP Cables, O2 Blenders, Endoscopes and Gas Analyzers. Pacific Medical carries the largest patient monitoring inventory in our industry and is recognized for its customer service response team.

For more information visit: www.pacificmedicalsupply.com.

PartsSource | Booth # 2209

PartsSource is a leading provider of supply chain solutions for medical replacement parts for providers, Independent Services Organizations and OEMs in the healthcare industry who need to innovate their procurement process to reduce their overall sourcing costs.

Physio-Control | Booth # 2306

LIFEPAK® defibrillator/monitors and automated external defibrillators from Physio-Control set the standard for quality and reliability and are used by more physicians, hospitals and emergency medical services than any other brand. Physio-Control continues to lead the industry through innovation and advanced technology. For more information, visit our website at www.physio-control.com.

Precision X-Ray | Booth # 1210

Precision X-Ray is the leading provider of safe, high output X-Ray irradiators used in modern translational cancer research. It’s our mission to continually develop X-ray systems that help researchers globally to better understand radiation induced effects in the sciences of molecular biology and cancer research.

PTW | Booth # 1220

Since 1922 PTW has been a dosimetry pioneer, growing into a global market leader for high-tech dosimetry solutions, well-known for their product excellence and innovative strength. Today, PTW dosimetry products are the first choice by healthcare professionals in radiotherapy, diagnostic radiology, nuclear medicine and health physics. For more information, visit www.ptwny.com.

Qfix | Booth # 1327

Qfix provides state-of-the-art patient positioning and immobilization devices to optimize patient outcomes. The Qfix kVue™ IGRT Couch Top design allows customization for individual patient needs through the most advanced array of treatment solutions for head and neck, breast, lung, prostate and other disease sites. Please visit www.Qfix.com for more information.

Radcal Corporation | Booth # 3204

Radcal is synonymous with quality non-invasive diagnostic x-ray meters and ion chambers. The Accu-Gold Family of meters utilizes Radcal ion chambers and solid-state Multisensors for all your parameter measurements in all modalities. The newest addition to the Family is the Accu-Dose+ and WiFi data transmission.

Radiological Imaging Technology Inc. | Booth # 1213

RIT manufacturers RIT113 Radiation Therapy Dosimetry software, and RADIA software for automated QC phantom analysis. RIT software packages are designed to enable QA on all aspects of modern radiation therapy and diagnostic imaging, including TG-142 for linear accelerators, TG-148 for helical tomotherapy, and ACR CT and MRI testing.

Raysearch Laboratories | Booth # 1219

RaySearch is a medical technology company that develops advanced software solutions for improved radiation therapy of cancer. RaySearch markets the RayStation® treatment planning system to clinics all over the world. In addition, RaySearch’s products are distributed through licensing agreements with leading medical technology companies. RaySearch’s software is used by over 2,500 clinics in more than 65 countries.

RTI (From Radiation to Information) | Booth # 1125

RTI provides complete quality assurance solutions for all X-ray modalities and facilities. We have “click & go” solutions for X-ray quality assurance of X-ray modalities and facilities. Everything between basic service to specialists. Our X-ray multimeter scan “do it all in one shot” – kV, time, dose, dose rate, HVL, pulsed fluoroscopy and total filtration.

Shimifrez | Booth # 2214

Shimifrez is the world’s most trusted name in micro, thin metal manufacturing, utilizing precision photo chemical machining (PCM). PCM produces highly accurate and identical thin metal components for small & large batches. PCM eliminates the cost of hard tooling, improves design flexibility and shortens lead times (72 hours) while eliminating burring and stress problems.

Southwest Medical Resources | Booth # 2210

Southwest Medical Resources is a world class independent service organization offering complete sales, service and rental solutions for Diagnostic Imaging Equipment. Our leadership in the industry is driven by a team of experts and unmatched resources. We exist to bring quality and value to our customers.

Spacelabs Healthcare | Booth # 2114

Spacelabs Healthcare’s philosophy is to develop innovative medical devices to provide the best care experience for not only the patient and the clinician, but also the patients’ families. Providing devices that help reduce stress can help enhance the experience for both patient and visitor alike.

Spectrum Technologies, Inc. | Booth # 2412

Spectrum Technologies, Inc. provides test instrument calibration and repair for the biomedical, commercial, and industrial markets. On-site services are available regionally and depot services are available worldwide. Our main office is in Pennsylvania with branch offices strategically located across the USA and two in Canada. Our website: www.goSTI.cc Email: info@goSTI.cc

Springer | Booth # 2311

Looking to publish your research? Discover Springer’s print and electronic publication services, including Open Access! Get high-quality review, maximum readership and rapid distribution. Visit our booth or springer.com/authors. You can also browse key titles in your field and buy (e)books at discount prices. With Springer you are in good company.

Standard Imaging | Booth # 1110

Dedication to customer service, forging partnerships and fostering innovation helps Standard Imaging pave an intuitive path to superior QA. Beginning with the HDR 1000 Well Chamber to the W1 Scintillator and PiPSpro Software today, Standard Imaging provides its customers with practical, precise products for their QA needs.
Sun Nuclear Corporation (SNC) | Booth # 1329

Sun Nuclear Corporation (SNC) is the worldwide market share leader in QA and Dosimetry solutions for Radiation Oncology. While others speak of innovation, we live it. Our mission is to provide you with better outcomes that save time. SNC supports FFF Beams, VMAT, IMRT, SRS, TomoTherapy, CyberKnife, and Conventional external beam treatments.

Synaptive Medical | Booth # 3404

Synaptive Medical has dedicated more than 50 engineers and scientists specifically to the development of neurosurgical technologies. The result? Our BrightMatter™ Neurosurgery Products provide advanced tools and information for surgeons and hospitals to focus on patient outcomes.

Technical Prospects | Booth # 2102

Technical Prospects has been in business over 18 years, providing quality Siemens parts and service to nearly 500 customers worldwide. As a well-known medical imaging parts reseller, our main objective is to provide quality parts and service, technical support, maintenance services and training to medical facilities and health care providers.

The Phantom Lab/Image Owl | Booth # 1209

The Phantom Laboratory (www.phantomlab.com) manufactures medical imaging and radiation therapy phantoms. In addition to our standard products we offer custom and OEM phantoms. We also work with Image Owl (www.imageowl.com) to provide fully automated, cloud-based, CT, MR and DBT image quality measurement and database services.

Tropical Health & Education Trust (THET) | Booth # 2511

THET is a specialist global health organisation that educates, trains and supports health workers through partnerships; enabling people in low and middle-income countries to access essential healthcare. THET helped develop the first Biomedical Engineering training course in Zambia and are working with Government to improve medical equipment management and maintenance.

University of Waterloo, Engineering | Booth # 2414

Waterloo Engineering is home to 60+ researchers focused in biomedical engineering and biotechnology, who produce advancements in pharmaceutical delivery systems, affordable imaging systems, software solutions for healthcare and more. With strong partnerships in industry, healthcare and government, our researchers create next-generation technology to tackle the world’s toughest biomedical problems.

USOC Medical | Booth # 2201

USOC Medical provides biomedical equipment repair solutions to healthcare facilities, clinics and medical companies of all types and sizes. We are committed to providing high-quality, cost-effective equipment and services to all of our clients. Each member of our organization is dedicated to excellence and continual organization and professional improvement.

Varian Medical Systems | Booth # 1234

Varian Medical Systems is a leading manufacturer of medical devices for treating cancer and other conditions with radiotherapy, radiosurgery, proton therapy, and brachytherapy. The company also produces informatics software for managing comprehensive cancer clinics. Varian is a premier supplier of tubes, digital detectors, and image processing workstations for X-ray imaging. www.varian.com
Western Medical Biophysics and BME | Booth # 3507

Welcome to Canada’s first Biophysics Department – home to 90 researchers and 100 graduate students. Working closely with research institutes and hospitals, we offer unique training opportunities in biomedical imaging, cardiovascular studies (microcirculation & hemodynamics), biomechanics, and cancer diagnosis & therapy, using a wide range of experimental and computational techniques.

World Congress 2018, Prague | Booth # 3311

The IUPESM World Congress 2018 will be held in Prague, Czech Republic on June 3 - 8, 2018. For constant updates please visit www.iupesm2018.org.

We invite you to visit our booth No. 3311 to try to win a FREE REGISTRATION for IUPESM 2018.

World Congress 2021, Candidate City - Mexico City | Booth # 3307

The Mexican Society of Biomedical Engineering (SOMIB) serves as the lead society and professional home for biomedical engineering. Our main mission is to promote and enhance knowledge and education in biomedical engineering nationwide and its utilization for human health and well-being. www.somib.org.mx

World Congress 2021, Candidate City – Singapore | Booth # 3614

Choose Singapore for 2021 World Congress - Singapore is excited to put forth a bid to host the IUPESM World Congress in 2021, the first time it will be held in South East Asia. We are ready to welcome the global community of medical physicists and biomedical engineers to our multi-cultural city.

World Congress 2021, Candidate City – Taipei | Booth # 3212

The IUPESM 2021 World Congress (WC-2021) has proposed to be hosted in Taipei, an international city with convenient and well-equipped facilities, by the Chinese Society of Medical Physics, Taipei and Taiwanese Society of Biomedical Engineering together. Many supports from local hospitals and related industrial companies will be offered for this important meeting. We believe that Taipei will be the optimum choice for this worldwide event in 2021.

World Health Organization | Booth # 3313

The World Health Organization is a U.N. specialized agency with a mandate as the directing and coordinating authority of international public health work. Through its 6 regional offices, 147 country offices, 8000+ staff, and collaborators the WHO strives towards: “Attainment by all peoples of the highest possible level of health.” The World Health Organization is a U.N. specialized agency with a mandate as the directing and coordinating authority of international public health work. Through its 6 regional offices, 147 country offices, 8000+ staff, and collaborators the WHO strives towards: “Attainment by all peoples of the highest possible level of health.”

Xoft, a subsidiary of iCAD, Inc. | Booth # 1129

iCAD delivers innovative cancer detection and radiation therapy solutions and services that enable clinicians to find and treat cancers earlier and while enhancing patient care. iCAD’s Xoft® Axxent® Electronic Brachytherapy (eBx®) System® delivers high dose rate, low energy radiation, which targets cancer while minimizing exposure to surrounding healthy tissue. For more information, visit www.icadmed.com.

Zimmer Canada | Booth # 2303

Founded in 1927 and headquartered in Indiana, Zimmer designs, develops, manufactures and markets orthopaedic reconstructive, spinal, trauma and dental implants, plus related surgical products. Zimmer has operations in more than 25 countries and sells products in more than 100 countries. The Company is supported by more than 8,500 employees worldwide.
Visit Elekta at the World Congress of Medical Physics and Biomedical Engineering 2015 in Toronto Canada and discover how we are bringing information-guided cancer™ care to you.

Stop by our booth # 1202 to learn more about the latest innovations in:

- Monaco® - Complete treatment planning system
- MOSAIQ® - Oncology information system
- AQUA - Machine quality management
- Oncentra® brachy planning (v4.5) - Comprehensive treatment planning for brachytherapy
- Flexitron® treatment delivery - Afterloading platform

Also, please join us for lunch where Stanley Benedict of University California Davis will discuss:

“New Technology Developments to Improve Patient Safety in Radiation Therapy”.

Learn how a better focus on safety in technology can deliver better precision, better reliability and better outcomes. This is an important guidance for Elekta and consistent with the stated goals of ASTRO, ACR and more.

Presenter:
Stanley H. Benedict, Ph.D., DABR, FAAPM
Professor & Vice Chair of Clinical Physics
Department of Radiation Oncology
University of California at Davis Comprehensive Cancer Center

June 9th, 2015
12:15 - 1:15 pm EST
Metro Toronto Convention
Center Room 718A

Please register at: http://www.elekta.com/wc2015symposium
### INDUSTRY SUPPORTED SYMPOSIA

**Program at a Glance**

- **THEME PLENARY KEYNOTE SESSION - GORDON MCBEAN & MARY GOSPODAROWICZ**
- **NETWORKING BREAK**
- **WORLD SUMMIT ON THE SUPPORT-ABILITY OF MEDICAL DEVICES**
- **CONTINUING EDUCATION SESSIONS (ENGLISH, FRENCH, SPANISH)**
- **IAPME GENERAL ASSEMBLY**
- **THEME PLENARY KEYNOTE SESSION - EDWARD SHORTLIFFE & VIMLA PATEL**
- **NETWORKING BREAK**
- **INDUSTRY SYMPOSIUM SUPPORTED BY CAREFUSION**
- **SCIENTIFIC SESSIONS INCLUDING PRESIDENT’S CALL**
- **IFMBE STUDENT DESIGN COMPETITION PRESENTATIONS**
- **CONTINUING EDUCATION SESSIONS (ENGLISH)**
- **ADDRESSING GLOBAL CHANGES**
- **CLOSING CEREMONY & YOUNG INVESTIGATORS AWARDS PRESENTATION**
- **GALA DINNER**
- **EXHIBIT & POSTER HALL HOURS**
  - **09:30 – 17:00**
Monday, June 8 2015

**PL01.1 Engaging Women and Men for a Better Future Worldwide**

**Speaker(s): Monique Frize**

Systems and Computer Engineering, Carleton University, Ottawa/ON/CANADA

From the three approaches suggested by Londa Schiebinger to harness the power of gender analysis, this part of the presentation deals with the first two: “Fixing the number of women” and “fixing the institutions”. Women and men can generate and participate in activities that lead to an increased participation of women in biomedical engineering and medical physics. Evidence also exists, demonstrating that there are economic benefits and more complete solutions created by gender balanced design teams and an increased number of women in decision-making bodies such as corporate boards, management teams in industry, government, and universities. It is critical to collect sex disaggregated data on undergraduate post-secondary enrolments and graduations in science and engineering, as well as to understand the gender participation in the workplace in these fields. Examining the issues that limit women’s participation at all levels is a first step, which can then be followed by the development and implementation of strategies that help eliminate gender bias and provide the necessary support for women to have a successful career in these fields.

**PL01.2 Gendered Innovations in Health & Technology**

**Speaker(s): Londa Schiebinger**

Stanford University, Stanford, United States of America

How can we harness the power of gender analysis to discover new things? Schiebinger identified three major approaches to gender in science research, policy, and practice: 1) “Fix the Numbers of Women” focuses on increasing women’s participation; 2) “Fix the Institutions” promotes gender equality in careers through structural change in research organizations; and 3) “Fix the Knowledge” or “gendered innovations” stimulates excellence in science and technology by integrating sex and gender analysis into research. This talk focuses on the third approach. Gendered Innovations: 1) develops state-of-the-art methods of sex and gender analysis for scientists and engineers; and 2) provides 24 case studies as concrete illustrations of how sex and gender analysis leads to new ideas and excellence in research. Several case studies will be discussed, including stem cells, assistive technologies for the elderly, and osteoporosis in men. All case studies can be found at: http://genderedinnovations.stanford.edu/. To match the global reach of science and technology, this project was developed through a collaboration of over sixty experts from across the United States, Europe, and Canada (and has now extended to Asia). Gendered Innovations was funded by the National Science Foundation, the European Commission, and Stanford University.
Tuesday, June 9 2015

PL02.1 Innovation, Healthcare and the Future
Speaker(s): Jeff Immelt
Chairman and CEO of GE, Fairfield/CT/UNITED STATES OF AMERICA

Jeff Immelt, Chairman & CEO of GE, will talk about healthcare innovation and how GE has been repositioning its business to succeed in a market that is demanding more technology, more flexibility and more tailored solutions.

Wednesday, June 10 2015

PL03.1 The Changing Urban Environment and Health in a Future Earth
Speaker(s): Gordon McBean
Western University, London/ON/CANADA

Around our planet there have been increasing numbers of disasters due to floods, storms, earthquakes and other natural hazards. Although earthquakes are most horrific when they happen, climate-related events cause about three-quarters of all disasters and as the climate warms, these hazards are increasing. There is also the migration to people to major cities, often on coasts of the oceans or major rivers. The result is the intersection of the effects of the major issues of climate change, disaster risk reduction and sustainable development. In all cases we need to look to the future and take actions now to reduce losses in the future.

In 2015, nations will negotiate a revised framework on action on disaster risk reduction, a possible Paris-protocol on climate change and Sustainable Development Goals to be attained by all countries by 2030. The draft list of SDGs includes: end poverty and hunger; attain healthy life for all at all ages; secure water and sanitation; and build inclusive, safe and sustainable cities and human settlements. For the global science community, the challenge is providing the scientific basis for definitions and approaches, including how to achieve these goals and the criteria for measurement of progress.

This presentation will bring together these issues in the context of the new international research programs Future Earth: Research for Global Sustainability; Integrated Research on Disaster Risk; and Health and Wellbeing in the Changing Urban Environment: a Systems Analysis Approach; with a Canadian-funded project, Coastal Cities at Risk: Building Adaptive Capacity for Managing Climate Change in Coastal Megacities. The Future Earth program is adopting an approach to involve the stakeholder community in the research program from the beginning to co-design and co-produce the research based on the logic that this will make the research most directly relevant to societies needs to address these issues. The Coastal Cities research project is integrating across social-natural-economic-engineering and health sciences to develop a systems approach to quantifying urban resilience and then undertake “what if” experiments to identify the most effective approaches to improving resilience and reducing impacts, recognizing the complex interactions across these elements of society.
The International Council for Science is leading the Science and Technology Major Groups to input to these UN processes and will endeavour to bring these scientific principles to the negotiations. Working with UN agencies such as UNESCO, UNU and WMO, and non-governmental partners such as the Inter-Academy Medical Panel, the Council will continue in the coming decades to assert the importance of scientific bases for these international agreements and national actions. We need to have the full support of medical physicists and biomedical engineers engaged in supporting health care in diverse environments in order to achieve these societal objectives, consistent with the Council’s Mission to strengthen international science for the benefit of society - all societies and all people.

Thursday, June 11 2015

SESSION DATE: THURSDAY, JUNE 11 2015
SESSION TIME: 13:30 - 15:00
SESSION ROOM: PLENARY HALL (HALLS F&G)
SESSION TITLE: PL04 - EVIDENCE AND HEALTH INFORMATICS
SPEAKER(S): EDWARD SHORTLIFFE & VIMLA PATEL

PL03.2 Cancer: The Global Health Challenge
Speaker(s): Mary Gospodarowicz

---

PL04.1 Academic Biomedical Informatics: Synergies and Challenges at the Interface with Industry
Speaker(s): Edward Shortliffe

Academic biomedical informatics has achieved great successes through research contributions and education of professional informaticians over several decades, now reflected in a thriving commercial marketplace for electronic health records and other informatics tools. That very success, coupled with changes in the ability of governments to support research at past levels, is forcing a reconsideration of the directions and emphases for faculty members in informatics academic units. In this presentation Dr. Shortliffe will discuss those forces and propose areas of emphasis that will strengthen the academic discipline as it continues to evolve. He will distinguish the roles of academic informaticians as practitioners of informatics, as researchers, and as educators. He will also stress the necessary synergies between academic informatics and the health information technology industry, arguing that both will be strengthened by more fertile relationships and joint efforts.
Given the complexities of modern medicine, delivery of safe and timely care is an ongoing and recognized challenge. Errors, misunderstandings, and inaccuracies—large and small—are routine occurrences in healthcare delivery. Health information technology (IT) has undoubtedly reduced the risk of serious injury for patients. However, its true potential for preventing medical errors remains only partially realized. Unfortunately, such systems may even give rise to hazards of their own. There is a growing recognition that many errors are attributable neither solely to lapses in human performance nor to flawed technology. Rather they develop as a product of the interaction between human beings and technology. In our view, errors are the product of cognitive activity in human adaptation to complex physical, social, and cultural environments. How well the design of health IT complements its intended setting and purpose is critically important for safe and effective performance. In this presentation, I will discuss the cognitive challenges we face in understanding human-computer interaction (HCI) that make the integration of computing and clinical practice a difficult task that, improperly addressed, can lead to threats to patient safety.
# SPECIAL SESSIONS

## Sunday, June 7 2015

**SESSION DATE:** Sunday, June 7 2015  
**SESSION TIME:** 08:00 - 17:15  
**SESSION ROOM:** 716  
**SESSION TITLE:** SS01 - USE OF AAPM TASK GROUP 100 RECOMMENDED RISK ASSESSMENT APPROACH TO DEVELOP A RISK BASED QUALITY MANAGEMENT PROGRAM IN RADIATION THERAPY  
**SESSION ORGANIZER(S):** SAIFUL HUQ

**SESSION DATE:** Sunday, June 7 2015  
**SESSION TIME:** 08:00 - 13:30  
**SESSION ROOM:** 715B  
**SESSION TITLE:** SS02 - AUTOSEG 2015  
**SESSION ORGANIZER(S):** STEPHEN BREEN & VLADIMIR PEKAR

**Introduction to Session:**  
This program will focus on automated methods for medical image segmentation. Topics will include: clinical applications, algorithms, and computational implementation.

Medical physicists, biomedical engineers, imaging scientists, computer scientists and healthcare professionals who use autosegmentation methods will enhance their knowledge and skills by attending this one-day event.

Ten leaders in autosegmentation will be presenting their latest methods and results.

After this event, attendees will be able to describe several autosegmentation algorithms; compare and evaluate different autosegmentation techniques; and select amongst different algorithms for varied imaging modalities and tasks.

**SESSION DATE:** Sunday, June 7 2015  
**SESSION TIME:** 13:30 - 18:00  
**SESSION ROOM:** 718A  
**SESSION TITLE:** SS03 - RT RESEARCH SYSTEM DEVELOPMENT ON OPEN-SOURCE SLICERRT PLATFORM  
**SESSION ORGANIZER(S):** GABOR FICTINGER AND CSABA PINTER

**SESSION DATE:** Sunday, June 7 2015  
**SESSION TIME:** 08:00 - 13:30  
**SESSION ROOM:** 715A  
**SESSION TITLE:** SS03 - RT RESEARCH SYSTEM DEVELOPMENT ON OPEN-SOURCE SLICERRT PLATFORM  
**SESSION ORGANIZER(S):** GABOR FICTINGER AND CSABA PINTER

**SESSION DATE:** Sunday, June 7 2015  
**SESSION TIME:** 13:30 - 18:00  
**SESSION ROOM:** 718A  
**SESSION TITLE:** SS04 - YIS PRESENTATIONS – JOINT IOMP & IFMBE
### Monday, June 8 2015

**Session Details:**
- **Session Date:** Monday, June 8 2015
- **Session Time:** 15:00 - 16:30
- **Session Room:** 714B
- **Session Title:** SS05 - European Initiatives in Medical Radiation Protection
- **Session Organizer(s):** Eugene Lief and John Damilakis

**Agenda:**
- **PIDRL:** A European Commission project on Paediatric DRLs
  - **Professor John Damilakis, EFOMP President.**
- **Overview of EFOMP projects on Radiation Protection**
  - **Professor Virginia Tsapaki, EFOMP**
- **Collaboration of AAPM and EFOMP on Radiation Protection Projects**
  - **Dr. Eugene Lief, AAPM**
- **Question and Answer time**

### Tuesday, June 9 2015

**Session Details:**
- **Session Date:** Tuesday, June 9 2015
- **Session Time:** 08:00 - 10:00
- **Session Room:** PLENARY HALL (HALLS F&G)
- **Session Title:** SS10 - IFMBE Awardees Presentations

**The Awardees will include:**
- IFMBE Laura M.C. Bassi Award: Alison Noble
- IFMBE Otto Schmidt Award: Karin Wardell
- IFMBE Vladimir Zworykin Award: Chwee Teck Lim
- IFMBE John A. Hopps Distinguished Service Award: Robert M. Nerem

---

**Session Details:**
- **Session Date:** Monday, June 8 2015
- **Session Time:** 16:00 - 18:00
- **Session Room:** PLENARY HALL (HALLS F&G)
- **Session Title:** SS07.1 - Presentation of 2021 Bids

**Session Details:**
- **Session Date:** Monday, June 8 2015
- **Session Time:** 18:00 - 19:00
- **Session Room:** PLENARY HALL (HALLS F&G)
- **Session Title:** SS07.2 - IUPESM Awardees Presentations

**The Awardees will include:**
- IUPESM Award of Merit - IFMBE recipient: Fumihiko Kajiya
- IUPESM Award of Merit - Medical Physics: Peter Smith
Introduction to Session:
For years, in-house clinical engineering (CE) departments and independent service organizations have faced several challenges. These relate to obtaining the supports required to service and maintain medical equipment in the field. To the CE community, providing safe, cost-effective, and expedient service depends on ability to obtain spare parts, service manuals, technical training, software, and access pass codes. It is becoming increasingly difficult to obtain these items. Manufacturers are placing conditions on servicing their products. Either no supports are provided or they charge very high prices to acquire them. Some companies will not allow servicing in the field unless expensive training is acquired. They create proprietary manuals and information separately for OEM eyes only and may charge even more to acquire this. Manufacturers contribute to the issue citing risks to the reliable support of their product. Purchasing agents are easily swayed by vendor claims of complexity that they and only they can service it (not field serviceable) and various other unfounded risks like “FDA won’t allow it.” Manufacturers and CE need to develop an understanding and common ground that will serve both sides so only the patient benefits.

Objectives
To discuss with Biomedical and Clinical Engineers, Physicists, Scientists, Academics, Healthcare Technology Managers, Healthcare Institutions, Manufacturers, Vendors, Independent Service, Organizations, Regulatory Agencies, Independent Research Organizations the issue of serviceability of Medical Devices.

The summit focus will be on questions below:
1. Is there a problem?
2. If so, how do we articulate it?
3. Define ‘Supportability’
4. Provide perspective from both sides

Impact on the Medical Device Industry
Medical equipment manufacturers may find a competitive edge when they fully support service of equipment in the field. When customers compare a vendor’s product, field supportability can be grounds for decision-making. Today’s devices and systems are becoming more and more similar from both hardware and software perspectives. The level of distinction among competing products and vendors is shrinking. Correspondingly, characteristics around the purchasing aspect have become increasingly apparent. From an in-house clinical engineering perspective, the vendor’s support for field supportability could make acquisition more efficient for in-house CE departments (less haggling). In-house service is known to reduce equipment cost of ownership in hospitals. This apply to all patient related technologies.

Supportability Defined
The level of ease to which a specific medical device or system is serviced by entities other than representatives or direct agents of the original equipment manufacturer (OEM).

AGENDA:

| REGULATION OF MEDICAL DEVICES | Nicolas PalliKarakis, University of Patras, Greece, and Chair HTA Division of IFMBE |
| Pre-market HTA of Medical Devices: an overview | Leandro Pecchia, University of Warwick, UK, and Treasurer of HTA Division of the IFMBE |
| From Monitoring the European Innovation Partnership on Active and Healthy Ageing (EIP on AHA) to early technology assessment | Christian Boehler, Joint Research Centre, European Commission, Seville, Spain |
| Multi-criteria decision analysis as a tool for medical devices assessment: a case study on R&D portfolio decision for new robotics in healthcare | Marjan Hummel, University of Twenty, The Nederlands |

### Special Session: SS16 - Addressing Global Challenges

**Introduction to Session:**
This Special Session “Addressing Global Challenges” will be presented by the past and current Chairs of the International Academy of Medical and Biological Engineering of the IFMBE.

The Opening Presentation by Robert Nerem is on “Bioengineering in the 21st Century”, followed by presentations on a variety of topics addressing global challenges from different perspectives including device technologies, information technologies, and innovative uses of physiological modeling.

#### Agenda:

### Special Session: SS17 - Spreading and Integrating Human Factors Expertise in Healthcare An International Panel Discussion

**Introduction to Session:**
Over the past decade, improving patient safety has been a priority for many healthcare organizations, but progress in the reduction of preventable patient harm has been slow. Human factors (HF) is recognized as an important scientific approach to improve health technology safety when applied to both pre-market (e.g., improved technology design), and post-market (e.g., improved practices, training and technology configuration/implementation) activities. HF is a discipline focused on improving safety by recognizing that humans are fallible, despite good intentions and hard work. It aims to build system resilience by focusing on the conditions under which people work and building defenses to minimize errors and their impacts.

While the potential for HF to improve healthcare safety is well established, it is not integrated and embedded in most safety initiatives. A possible explanation for this unfulfilled potential is that there are limited HF experts working in healthcare. Most HF-related work to date is done at a few organizations in a few countries (i.e., organizational silos). In addition, there has been a lack of formal professional collaboration between HF experts, patient safety leaders, regulators, clinicians, and health technology managers and designers, resulting in disparate expertise (i.e., professional/expertise silos). As such, there is a need to spread HF expertise internationally and across healthcare-related professions (e.g., clinical engineers, biomedical technicians, designers) so they can be empowered to take more active roles in initiating and leading safety projects that incorporate HF.

HumanEra, an HF team based at the University Health Network in Toronto, Canada, has been teaching HF to various healthcare sectors and stakeholders for almost 10 years. Teaching tactics have included:

- Introductory HF workshops
- HF method courses
- Partnering with healthcare organizations to build in-house HF teams/expertise (multi-year contracts focused on project-based collaborations)
- An introductory HF book (expected publication late 2015)

This session will consist of a panel of HumanEra teachers and past international students to share our combined experiences in teaching, learning, and applying HF for the first time to a safety initiative. The panel will include representatives from different sectors (e.g., academics, clinical engineers, regulators, designers/vendors) and countries (e.g., Canada, Brazil, Spain).
By attending this session you will:

- Discover how HF can improve healthcare safety
- Learn from the panel's experience about applying HF in their different roles/professions, organizations, and/or jurisdictions
- Contribute to meaningful discussions about how you can become an HF champion and help to accelerate the adoption of HF in your organization
- Meet international professionals interested in HF collaboration to contribute to the cross-fertilization of this important field

**AGENDA:**

**Overview:**
A brief introduction to HF will be provided (e.g., define HF for the healthcare context)

**Presentations:**
Each panel member will present a short summary of their experience in promoting and applying HF to healthcare, focusing on their successes and barriers.

**Interactive discussion:**
The presentations will serve as a springboard for an interactive discussion between panel members and the audience.

*Moderated by Dr. Patricia Trbovich*

**SESSION ORGANIZER(S):** MARIA LINDEN
Introduction to Session:

The World Biomedical Engineering and Medical Physics Leaders’ Summit is the inaugural tri-annual high-level policy meeting dedicated exclusively to furthering the role of biomedical engineering and medical physics in medicine. This unique event brings together key decision makers, academics, and practicing engineers and physicists from around the globe and encourages timely debate on emerging issues related to the development and sustainability of the role and impact of medical physicists and biomedical engineers in medicine and healthcare. The Summit provides a unique and important forum to secure a coordinated, multileveled global response to the need, demand, and importance of creating and supporting strong academic and clinical teams of biomedical engineers and medical physicists for the benefit of human health.

Key Objectives of the Leaders’ Summit:

- Raising awareness among leading decision makers to ensure the role of biomedical engineering and medical physics is recognized as a local, regional, and global health priority.
- Providing a forum to exchange information and innovative ideas on how to create and sustain academic and clinical programs in medical physics and biomedical engineering.
- Creating a force that galvanizes the leadership and decision-makers in academia, industry, and medicine to assure the role of these two translational and impactful disciplines expand their impact on human health.
- Defining compelling messages to support the critical role that biomedical engineers and medical physics play in supporting and advancing human health.

10:30  JT04.1: Ethics for Biomedical Engineers and Medical Physicists Workshop
       Jean-Pierre Bissonnette, Canada
       Monique Frize, Canada

10:30  MPS09.1: Peripheral Neutron and Photon Doses
       Beatriz Sanchez Nieto, Chile

10:30  MPS08.1: Curriculum Design: How to Train the Next Generation of Physicists?
       Maria Ester Brandan, Mexico

10:30  BMEE06.1: Regulatory Issues in Biocompatibility
       Paul Santerre, Canada

10:30  MPF08.1: Algorithmes de Calcul de Dose, Incluant Monte Carlo
       Raphaelle Moekli, Switzerland

11:30  MPF08.2: Utilisation de la Maîtrise Statistique des Processus en Milieu Hospitalier
       Karine Herlevin (Gérard), France

13:30  BMEE07.1: E-medicine and Remote Medical Consultations
       Gilad Epstein, Canada

13:30  MPS09.1: The Modern Physicist Tool Box: How to Choose Between Current Dosimeters
       Faustino Gómez, Spain

13:30  MPS08.1: Curriculum Design: How to Train the Next Generation of Physicists?
       Maria Ester Brandan, Mexico

13:30  BMEE06.1: Regulatory Issues in Biocompatibility
       Paul Santerre, Canada

13:30  MPF08.1: Algorithmes de Calcul de Dose, Incluant Monte Carlo
       Raphaelle Moekli, Switzerland

11:30  MPF08.2: Utilisation de la Maîtrise Statistique des Processus en Milieu Hospitalier
       Karine Herlevin (Gérard), France

15:00  BMEE08.1: Biomechanics - Implant design
       Cheng-Kung (Richard) Cheng, Chinese Taipei

13:30  MPS10.1: The Modern Physicist Tool Box: How to Choose Between Current Dosimeters
       Faustino Gómez, Spain

13:30  MPS10.1: The Modern Physicist Tool Box: How to Choose Between Current Dosimeters
       Faustino Gómez, Spain

14:30  MPS10.2: Dosimétrie et Radioprotection en Radiologie
       Sylvain Deschênes, Canada

15:00  BMEE08.1: Biomechanics - Implant design
       Cheng-Kung (Richard) Cheng, Chinese Taipei

13:30  MPS09.1: The Modern Physicist Tool Box: How to Choose Between Current Dosimeters
       Faustino Gómez, Spain

14:30  MPS09.2: Dosimétrie et Radioprotection en Radiologie
       Sylvain Deschênes, Canada

15:00  BMEE08.1: Biomechanics - Implant design
       Cheng-Kung (Richard) Cheng, Chinese Taipei

13:30  MPS08.1: Curriculum Design: How to Train the Next Generation of Physicists?
       Maria Ester Brandan, Mexico

14:30  MPS08.2: Utilisation de la Maîtrise Statistique des Processus en Milieu Hospitalier
       Karine Herlevin (Gérard), France

15:00  BMEE08.1: Biomechanics - Implant design
       Cheng-Kung (Richard) Cheng, Chinese Taipei

13:30  MPS07.1: What can IAEA do for the Clinical Medical Physicist?
       Joanna Izewksa, Austria

14:20  MPS07.2: Safety Learning and Safety Management to Prevent Radiotherapy Incidents
       Ola Holmberg, Austria

15:20  MPS07.3: Equipment Standards and Performance Measurements for Radiotherapy
       Jean Moran, United States
15:00  BMEE09.1: Medical Device Network Connectivity  
      Ryan Forde, United States

15:00  MPE08.1: Quality Systems in Radiotherapy  
      Mary Coffey, Ireland

15:00  MPS11.1: Dosimetry Under Non-Reference Conditions  
      Faustino Gómez, Spain

15:00  MPF10.1: La Radiothérapie Guidée par L’image,  
      Incluant Doses et CQ  
      Myriam Ayadi-Zahra, France

15:00  BMEE10.1: Multiscale Biomechanics in Deep Tissue  
      Injuries  
      Arthur Mak, Hong Kong

17:00  BMEE11.1: Trends in Medical Device Certification and  
      improving Patient Safety through Evolving Standards  
      Dale Morgan, Canada

17:00  MPE09.1: The Modern Physicist Tool Box:  
      How to Choose Between Current Dosimeters  
      Jan Seuntjens, Canada

17:30  MPE09.2: Radiobiology Applications for Clinical  
      Physicists: Isoeffective dose calculations;  
      Hypofractionation; TCP/NTCP; Peripheral doses  
      and secondary cancers  
      Michael Joiner, United States

18:00  BMEE12.1: Clinical Engineers & Biomedical Engineering  
      Technologists Certification - International Perspective  
      Larry Boyce, Canada  
      Petr Kresta, Canada

ADVANCING RADIATION THERAPY THROUGH SOFTWARE INNOVATION

Monday, June 8, 2015
At 12:15 to 13:15
Metro Toronto Convention Centre, South Building
Room 718A
Lunch will be provided

12:15 - 12:35
Considerations for implementing adaptive therapy using RayStation
Bon Mzenda, Chief Physicist
Auckland Radiation Oncology, Auckland, New Zealand

12:35 - 12:55
Deformable Image Registration and Dose Accumulation
Jean-Pierre Bissonnette & Vicky Kong
Radiation Medicine Program
Princess Margaret Cancer Center, Toronto Canada

12:55 - 13:15
Advancing radiation therapy through software innovation
Johan Löf, CEO
RaySearch Laboratories AB, Stockholm, Sweden

Moderator: Marc Mlyn, CEO, RaySearch Americas Inc.

www.raysearchlabs.com
## SCIENTIFIC PROGRAM

SCI. PROGRAM BY TRACK
Monday, June 8 2015

SESSION TIME: 08:00 - 09:30
SESSION ROOM: 718A
SESSION TRACK: TRACK 01: IMAGING
SESSION NAME: SP001 - IMAGE PROCESSING AND VISUALIZATION: PART 1
SESSION CHAIR(S): MARLEN PEREZ-DIAZ, CUBA

08:00 SP001.1 - The Use of Wavelet Filters for Reducing Noise in Posterior Fossa Computed Tomography Images
*Marlen Perez-Diaz, Cuba*

08:15 SP001.2 - Automatic Liver Localization based on Classification Random Forest with KNN for Prediction
*Fucang Jia, People’s Republic of China*

08:30 SP001.3 - Brain Tumor Target Volume Segmentation: Local Region Based Approach
*Hossein Aslian, Italy*

08:45 SP001.4 - A Novel Automatic White Balance Algorithm for the 3D Image of Stereoscopic Endoscopy
*Ling Li, People’s Republic of China*

09:00 SP001.5 - A new log-compression rule for B-mode ultrasound imaging adjusted to the human visual system
*Ramon Fernandes, Brazil*

09:15 SP001.6 - Comparison of Independent Component Analysis (ICA) Algorithm for Heart Rate Measurement Based on Facial Imaging
*Septiana, Indonesia*

SESSION TIME: 08:00 - 09:45
SESSION ROOM: 701A
SESSION TRACK: TRACK 02: BIOMATERIALS AND REGENERATIVE MEDICINE
SESSION NAME: SP002 - STEM CELLS IN TISSUE ENGINEERING AND REGENERATION
SESSION CHAIR(S): GILDA BARABINO, UNITED STATES

08:00 SP002.1 - KEYNOTE: Biomaterials and Regenerative Medicine: Micro-environmental Modulation for Controlled Cell Differentiation and Tissue Development
*Gilda Barabino, United States*

08:30 SP002.2 - KEYNOTE: Defining the regulatory metrics for regenerative medicine using novel biomaterial tagging strategies
*Alicia El Haj, United Kingdom*

09:00 SP002.3 - The role of electric fields in promoting precursor cell migration to enhance wound repair
*Stephanie Iwasa, Canada*

09:15 SP002.4 - The role of niche architecture on muscle stem cell division orientation
*Richard Cheng, Canada*

09:30 SP002.5 - Mapping the Stem Cell’s Mechanome using Paired Live Cell Multiplexed Imaging and Modeling
*Melissa Knothe Tate, Australia*

SESSION TIME: 08:00 - 09:45
SESSION ROOM: 701B
SESSION TRACK: TRACK 04: RADIATION ONCOLOGY
SESSION NAME: SP003 - BRACHY THERAPY: PART 1
SESSION CHAIR(S): SIJI PAUL, INDIA

08:00 SP003.1 - The impact of in-homogeneity corrected dose calculations for various clinical HDR brachytherapy sites.
*Siji Paul, India*

08:15 SP003.2 - A novel QA device for brachytherapy applicator QA
*Sook Kien Ng, United States*

08:30 SP003.3 - Electromagnetic tracking for catheter reconstruction in ultrasound-guided high-dose-rate brachytherapy of the prostate
*Alexandru Nicolae, Canada*

08:45 SP003.4 - Dosimetric and radiobiological comparison of volumetric modulated arc therapy, high-dose-rate brachytherapy and low-dose-rate permanent seeds implant for localized prostate cancer
*Ruijie Yang, People’s Republic of China*

09:00 SP003.5 - A novel system for real-time planning and guidance of breast HDR brachytherapy
*Eric Poulin, Canada*
09:15  SP003.6 - Investigation of electromagnetic catheter tracking approach for spatial reconstruction of implant geometry in high dose rate brachytherapy of prostate cancer

Gabor Fichtinger, Canada

09:30  SP003.7 - Endoscopic Tracking for improved Applicator Insertion in Esophagus and Lung HDR Brachytherapy

Robert Weersink, Canada

08:00  SP004.1 - In Vivo EPID Dosimetry Detects Interfraction Errors in 3D-CRT of Rectal Cancer

Stefano Peca, Canada

08:15  SP004.2 - Establishing action thresholds for patient anatomy changes and machine errors during complex treatment using EPID and gamma analysis

Ophélie Piron, Canada

08:30  SP004.3 - Dosimetrical characteristics of amorphous silicon electronic portal imager for flattening filter free (FFF) photon beam of upgraded C-series Linear accelerator

Vellian Subramani, India

08:45  SP004.4 - Radiation field size, junction and MLC QA using amorphous silicon electronic portal imaging device, an efficient approach to improve routine accuracy

Dany Simard, Canada

09:00  SP004.6 - Real-time detection of deviations in radiotherapy beam delivery using a head-mounted detector

Richard Canters, Netherlands

08:15  SP005.2 - Influence of Jaw Tracking in Intensity Modulated and Volumetric Modulated Arc Radiotherapy for Head and Neck Cancers? A Dosimetric Study

Kh Anamul Haque, Bangladesh

08:30  SP005.3 - Evaluation of the eye lens dose according to patient setup errors in pediatric head CT examination

Rumi Gotanda, Japan

08:45  SP005.4 - Multi-Point Sources on Skin to Assess the Annual Effective Dose by Usage of TENORM added Pillow

Do hyeon Yoo, Republic of Korea

09:00  SP005.5 - Patient-Specific Quality Assurance of Respiratory-Gated VMAT Using a Programmable Cylindrical Respiratory Motion Insert for the ArcCHECK™ Phantom

Heather Young, Canada

08:00  SP006.1 - KEYNOTE: Dosimetry and Radiation Protection

Virginia Tsapakis, Greece

08:30  SP006.2 - Organ dose reduction while using in-house CBCT patient-specific protocols based on OSL dosimetry

Étienne Létourneau, Canada

08:45  SP006.3 - A novel tool for in vivo dosimetry in diagnostic and interventional radiology using plastic scintillation detectors

Jonathan Boivin, Canada

09:00  SP006.5 - Assessment of patient’s eye lens dose using a custom made anthropomorphic head phantom

Kwan Hoong Ng, Malaysia

09:15  SP006.6 - Dose Profile and Equilibrium Doses in CT

Ricardo Terini, Brazil

08:00  SP0005.1 - Verifying dynamic planning in gamma knife radiosurgery using gel dosimetry

Gopishankar Natanasabapathi, India
08:00  SP007.1 - **KEYNOTE**: Biosignal Processing  
*Adrian Chan, Canada*

08:30  SP007.2 - Adaptive filter for eliminating baseline wander of pulse wave signals  
*Anna Akulova, Russian Federation*

08:45  SP007.3 - Efficacy of DWT denoising in the removal of power line interference and the effect on morphological distortion of underlying atrial fibrillatory waves in AF-ECG  
*Omar Escalona, United Kingdom*

09:00  SP007.4 - Quantifying Blood-Oxygen Saturation Measurement Error in Motion Contaminated Pulse Oximetry Signals  
*Geoffrey Clarke, Canada*

09:15  SP007.5 - Signal Quality Indices for Ambulatory Electrocardiograms used in Myocardial Ischemia Monitoring  
*Mohamed Abdelazez, Canada*

09:30  SP007.6 - A simple algorithm for identifying artifact beats in long ECG recordings  
*Nini Rao, People’s Republic of China*

09:45  SP007.7 - Automatic Detection of Low-Quality Seismocardiogram Cycles Using the Outlier Approach  
*Vahid Zakeri, Canada*

08:00  SP008.1 - A Validation Test of a Simple Method of Stride Length Measurement Only with Inertial Sensors and a Preliminary Test in FES-assisted Hemiplegic Gait  
*Takashi Watanabe, Japan*

08:15  SP008.2 - A novel Treadmill Body Weight Support system using Pneumatic Artificial Muscle actuators: a comparison between active Body Weight Support system and counter weight system  
*Thuc Tran, Japan*

08:30  SP008.3 - A Serious Game for Training and Evaluating the Balance of Hemiparetic Stroke Patients  
*Pedro Bertemes-Filho, Brazil*

08:45  SP008.4 - fNIRS-based analysis of brain activation with knee extension induced by functional electrical stimulation  
*Misato Ohdaira, Japan*

09:00  SP008.5 - Muscle fatigability of isometric and isokinetic knee-extension generated by single-electrode- and spatially-distributed-sequential-stimulation  
*Austin Bergquist, Canada*

09:15  SP008.6 - External modulation of electrical stimulated spinal reflexes - a control modality for human lumbosacral networks in injury induced disconnection from brain control  
*Winfried Mayr, Austria*

09:30  SP008.7 - Motor Control Assessment using Leap Motion: Filtering Methods and Performance in Indoor and Outdoor Environments  
*Jone Kim, Canada*

09:45  SP008.8 - Biceps brachii EMG signals: estimation of dipole sources  
*Peyman Aghajamaliaval, Canada*

10:00  SP008.9 - Validating a Solid-Static Single-Armed Male Prototype Tasked to Produce Dynamic Movement from the Shoulder Through the Preparation Phase  
*Alicia Gal, Canada*

16:00  SP018.4 - Tissue characterization using dual energy cone beam CT imaging with a dedicated small animal radiotherapy platform  
*Patrick Granton, Canada*

16:15  SP018.5 - Low-dose prostate cancer brachytherapy by injections of radioactive gold nanoparticles (103Pd:Pd@Au NPs)  
*Myriam Laprise-Pelletier, Canada*

---

**SESSION TIME:**  15:00 – 16:30  
**SESSION ROOM:**  717B  
**SESSION TRACK:**  TRACK 08: BIOSENSOR, NANOTECHNOLOGY, BIOMEMS AND BIOPHOTONICS  
**SESSION NAME:**  SP019 - NANOBIOSENSORS AND NANOTHERANOSTICS  
**SESSION CHAIR(S):**  KWANG OH, UNITED STATES  
WALTER H. CHANG, CHINESE TAIPEI

15:00  SP019.1 - Synthesis and evaluation of C595 mAb-conjugated SPIONs nanoprobe for specific detection of Prostate cancer  
*Mohammad Abdollahi, Iran*

15:15  SP019.2 - Magnetic Resonance Nanotheranostics of Guerin's Carcinoma  
*Valerii Orel, Ukraine*

15:30  SP019.3 - Effects of Fluorescence Gold Nanoclusters on Anti-oxidation and Anti-aging by Cell Model  
*Walter H. Chang, Chinese Taipei*

15:45  SP019.4 - Nanoparticle-aided Radiotherapy for Retinoblastoma and Choroidal Melanoma  
*Wilfred Ngwa, United States*

16:00  SP019.5 - Nanoparticle enhancement of radiation dose: experimental confirmation using scintillation dosimetry  
*Natalka Suchowerska, Australia*

16:15  SP019.6 - Graphene Plasmonics as Promising Platform for Highly Sensitive Plasmonic Sensing  
*Dong Ha Kim, Republic of Korea*

---

**SESSION TIME:**  15:00 – 16:45  
**SESSION ROOM:**  715B  
**SESSION TRACK:**  TRACK 09: BIOSIGNAL PROCESSING  
**SESSION NAME:**  SP020 – BIOMEDICAL MODELING  
**SESSION CHAIR(S):**  RUI FONSECA-PINTO, PORTUGAL  
KYUICHI NIIZEKI, JAPAN

15:00  SP020.1 - Respiratory parameters have different patterns in imposed-inspiration and imposed-expiration within a closed pneumatic circuit in rats  
*Fabio Aoki, Brazil*

15:15  SP020.2 - Autonomic and cardiovascular responses to food ingestion and gum chewing in healthy young subjects  
*Kyuichi Niizeki, Japan*

15:30  SP020.3 - Characteristic Analysis and Modeling for Signals of Auditory Propagation Pathway  
*Qin Gong, People's Republic of China*

15:45  SP020.4 - Numerical Optimization Performance of a Perfusion Kinetic Modelling Algorithm using Volumetric DCE CT  
*Igor Svistoun, Canada*

16:00  SP020.5 - Validation of a Sympathovagal Balance Model to Evaluate Autonomic Function in Rats Using Time-Frequency Analysis  
*Rui Fonseca-Pinto, Portugal*

---

**SESSION TIME:**  15:00 – 16:15  
**SESSION ROOM:**  716B  
**SESSION TRACK:**  TRACK 13: INFORMATICS IN HEALTH CARE AND PUBLIC HEALTH  
**SESSION NAME:**  SP021 – PUBLIC HEALTH, ACTIVE AND HEALTHY AGING  
**SESSION CHAIR(S):**  ELINA KALDOUDI, GREECE  
CHRISTIAN BOEHLER, SPAIN

15:00  SP021.1 - KEYNOTE: Informatics in Health Care and Public Health  
*Leandro Pecchia, United Kingdom*

15:30  SP021.2 - Monitoring Information System of Aedes Aegypti Reproduction  
*Lourdes Brasil, Brazil*

15:45  SP021.3 - Design and Functionality of a Meta-Reporting Tool within a Medical Devices Vigilance System  
*Aris Dermitzakis, Greece*

16:00  SP021.4 - Evaluation of the Impact in the Physical Condition of School Age Children Exposed to an Intervention of Exergaming in Montemorelos Mexico  
*Gerardo Romo-Cardenas, Mexico*

16:15  SP021.5 - Using the EIP on AHA monitoring tool for the early technology assessment of a planned device to predict in-hospital falls in the elderly  
*Christian Boehler, Spain*

16:30  SP021.6 - An innovative Decision Support System (DSS) for patients with Inflammatory Bowel Disease (IBD)  
*Vasileios Tsianos, Greece*
15:00  SP022.1 - Biomedical Engineering in Nigeria: A Developmental Overview  
*Kenneth Nkuma-Udah, Nigeria*

15:15  SP022.2 - Modernising Scientific Careers? A new scheme for the education and training of physicists, engineers and other scientific staff in the UK National Health Service  
*Keith Ison, United Kingdom*

15:30  SP022.3 - Medical Physics Residency Program in Developing Countries: Lessons, Challenges and Solutions Learned from a Regional Pilot Training Program  
*Belal Moftah, Saudi Arabia*

15:45  SP022.4 - International Union of Biological Sciences  
*Nils Chr. Stenseth, France*

16:00  SP022.5 - Promoting the public image of Medical Physicists and Biomedical Engineers  
*Micah Cheng, Canada*

16:15  SP022.6 - The Utilization and Design of Doorless Mazes for Medical Linear Accelerator Rooms In Ontario, Canada  
*Joseph Szabo, Canada*

---

17:00  SP023.1 - Improving quantitative functional imaging with dynamic contrast enhanced studies using a linearized Johnson-Wilson model approach  
*Fiona Li, Canada*

17:15  SP023.2 - Early tumor Response assessment using volumetric DCE-CT and DCE-MRI in Metastatic Brain Cancer Patients  
*Catherine Coolens, Canada*

17:30  SP023.3 - Diffusion tensor imaging is correlated with quantitative histology in surgically-rectested hippocampi of epilepsy patients  
*Terry Peters, Canada*

---

17:45  SP023.4 - Evaluation of fully automatic volumetric GBM segmentation in the TCGA-GBM dataset: Prognosis and correlation with VASARI features  
*Emmanuel Rios Velazquez, United States*
17:30 SP025.3 - A Geant4 Helical Tomotherapy model as a tool for 3D dose distribution evaluation
   Alessandro Esposito, Portugal

17:45 SP025.4 - Development of 4D actual delivered dose calculation system for dynamic tumor-tracking irradiation with a gimballed linac
   Yoshitomo Ishihara, Japan

18:00 SP025.5 - Organ Doses from Hepatic Radioembolization with Y-90, Sm-153, Ho-166 and Lu-177: A GEANT4 Monte Carlo Simulation Study
   Chai Hong Yeong, Malaysia

18:15 SP025.6 - Stereotactic Ablative Radiotherapy (SABR) for lung cancer using Volumetric Modulated Arc Therapy (VMAT) with a 10x Flattening Filter Free (FFF) beam: validation of the calculated dose distribution using Monte Carlo
   Tony Mestrovic, Canada

18:30 SP025.7 - Performance of the ACUROS® dose calculation algorithm for 6 MV FFF beams in inhomogeneous media
   Matthew Schmid, Canada

18:45 SP025.8 - Ray Tracing Algorithm for Virtual Source Modelling based on Evaluation of Rounded Leaf End Effect of Multileaf Collimator
   Dong Zhou, People’s Republic of China

17:00 SP026.1 - The Development of a Device for the Fricke Dosimetry for HDR Brachytherapy
   Camila Salata, Brazil

17:15 SP026.2 - A New Methodology for the Determination of the G-value for Fricke Dosimetry
   Camila Salata, Brazil

17:30 SP026.3 - The Use of Fricke Dosimetry as a Primary Standard for the Absorbed Dose to Water for 192Ir HDR-BT Sources: Determination of the G-value
   Camila Salata, Brazil

17:45 SP026.4 - IAEA Dosimetry Laboratory support to the IAEA/WHO SSDL Network
   Joanna Izewska, Austria

18:00 SP026.5 - Measurement of Wair in high energy electron beams
   Claudiu Cojocaru, Canada

18:15 SP026.6 - Monte Carlo corrections for a Fricke-based standard of absorbed dose to water for Ir-192 HDR brachytherapy.
   Ernesto Mainegra-Hing, Canada

18:30 SP026.7 - Changes in absorbed dose to water caused by dose standard shift for ionization chamber calibration in Japan
   Hidetoshi Saitoh, Japan

18:45 SP026.8 - A calibration system of therapy-level dosimeter in Japan organized by ANTM
   Suoh Sakata, Japan
17:00 SP028.1 - On Understanding of the Limiting Factors in Radiofrequency Ablation on Target Tissue Necrosis Volume
Bing Zhang, People’s Republic of China

17:15 SP028.2 - Thermal Dose Based Monitoring of Thermal Therapy for Prostate Cancer
Joseph Kumaradas, Canada

17:30 SP028.3 - Nanodrug Delivery and Anti-tumor Efficacy for Brain Metastasis of Breast Cancer Enhanced by Short-time Low-dose Ultrasound Hyperthermia
Sheng-Kai Wu, Chinese Taipei

17:45 SP028.4 - Evaluating breast cancer surgical margins using high-frequency ultrasound: Statistical analysis of a 17-patient pilot study
Robyn Omer, United States

18:00 SP028.5 - The Intraoperative Detection of Breast Cancer in Surgical Margins Using High-Frequency Ultrasound: Studies Using Histology Mimicking Phantoms
Zachary Coffman, United States

18:15 SP028.6 - Rapid Molecular Subtyping of Breast Cancer Using High-Frequency Ultrasound (10-120 MHz) and Principal Component Analysis
Caitlin Carter, United States

18:30 SP028.7 - Inverse treatment planning using radiofrequency ablation in cancer therapy
Shefali Kulkarni-Thaker, Canada

17:15 SP029.2 - Seymour Shield? An Operative Adjunct Device for Maintaining Visualization during Laparoscopic Surgery
Karthik Kannan, Singapore

17:30 SP029.3 - Optimizing MRI-targeted fusion prostate biopsy: the effect of systematic error and anisotropy on tumour sampling
Peter Martin, Canada

17:45 SP029.4 - Is hemolysis influenced by the dynamic calibration method of CPB roller pumps?
Eduardo Costa, Brazil

18:00 SP029.5 - A Fiducial Apparatus for 6DOF Pose Estimation of an External Echo Probe from a Single X-ray Projection: Initial Simulation Studies on Design Requirements
Charles Hatt, United States

18:15 SP029.6 - Mechanism design a flexible endoscope with USB adaptation to training.
Francisco Perez Reynoso, Mexico

18:30 SP030.1 - KEYNOTE: Drop-based microfluidics for diagnostic applications
David Weitz, United States

17:00 SP030.2 - Enhanced multielectrode configurations in miniaturized 3D electrical impedance spectroscopy and tomography? Monitoring the overall process of tissue engineering with spatial sensing for future challenges in microfluidics
Chiara Canali, Denmark

17:45 SP030.3 - On-line monitoring of 2D and 3D cell cultures: electrode configurations for impedance based sensors
Chiara Canali, Denmark

18:00 SP030.4 - Development of Microfluidic Paper-Based Electrochemical Immunoassays for the Detection of Prostate Cancer
Sean Rawlinson, United Kingdom

18:15 SP030.5 - Investigating chip design for a Raman microfluidic system with clinical radiobiological applications.
Samantha Harder, Canada
18:30 SP030.6 - A lab-on-a-chip system for hypoxic investigations on single biological cells
   Ahmed Alrifaiy, Sweden

18:45 SP030.7 - Gas Sensors with ZnO Quantum Dots Synthesized by Sol-Gel Methods
   Lourdes Brasil, Brazil

17:00 SP031.1 - The Recognition of Pinch-to-Zoom Gesture Based on Surface EMG
   Jongin Kim, Republic of Korea

17:15 SP031.2 - Feature extraction trends for biomedical signals
   Yashodhan Athavale, Canada

17:30 SP031.3 - A Hybrid Model for Diagnosing Sever Aortic Stenosis in Asymptomatic Patients using Phonocardiogram
   Maria Lindén, Sweden

17:45 SP031.4 - Classification of Load in Hands Based on Upper Limb SEMG
   Illya Seagal, Canada

18:00 SP031.5 - An Intelligent Method for Discrimination between Aortic and Pulmonary Stenosis using Phonocardiogram
   Amir Sepehri, Belgium

17:00 SP032.1 - KEYNOTE: Neuroprosthetic Systems for Enhancement of Neuroplasticity Following Stroke and Spinal Cord Injury
   Milos Popovic, Canada

17:30 SP032.2 - Demonstration of Graphene Microelectrodes as a Bioelectronic Interface
   Michael Horn, United States

17:45 SP032.3 - Development of a planar microelectrode array offering long-term, high-resolution neuronal recordings
   Pierre Wijdenes, Canada

18:00 SP032.4 - Morphological changes in photoreceptors due to DC electric field
   Juliana Guerra, Brazil

18:15 SP032.5 - Accelerating Neurite Outgrowth Through Electric Field Manipulation
   Michael Purdy, Canada

### SP035.1 - Detectability in SPECT Myocardial Perfusion Imaging: Comparison between a Conventional and a Semiconductor Detector System

**Ana Marques Da Silva, Brazil**

08:00

### SP035.6 - An alternate mathematical modeling of image formation, and framework for performance analysis of positioning algorithms in the scintillation camera

**Mohammad Reza Ay, Iran**

08:15

### SP035.3 - Apodized-Aperture Pixel Design of an X-Ray Detector with Enhanced High-Frequency DE and Reduced Noise Aliasing

**Elina Ismailova, Canada**

08:30

### SP035.4 - Geant4 Simulations of Scintillation Light Collection and Extraction in PET/CT Detectors

**Francis Loignon-Houle, Canada**

08:45

### SP035.5 - LabPETII.5: APD-based Detector Characterization for Pre-clinical PET Imaging

**Émilie Gaudin, Canada**

09:00

### SP035.2 - The performance of the CMOS APS detector for dual energy contrast enhanced digital mammography

**Ilias Billas, United Kingdom**

09:15

---

**SESSION TIME:** 08:00 – 10:00

**SESSION ROOM:** 718A

**SESSION TRACK:** TRACK 01: IMAGING

**SESSION NAME:** SP034 – CT: NEW TECHNIQUES

**SESSION CHAIR(S):** MOHAMMAD REZA AY, IRAN

### SP034.1 - Design, modeling and performance evaluation of a small animal Micro-CT scanner: A Monte Carlo study

**Mohammad Reza Ay, Iran**

08:00

### SP034.2 - An imaging method by using electron mode of linear accelerator for soft tissue emphasis

**Atsushi Myojoyama, Japan**

08:15

### SP034.3 - Anatomical noise model for CT head images: preliminary results

**Marlen Perez-Díaz, Cuba**

08:30

### SP034.4 - The potential of spectral-CT for material decomposition with gold-nanoparticle and iodine contrast

**Byungdu Jo, Republic of Korea**

08:45

### SP034.5 - Spatial Resolution Studies for a Prototype Proton CT Scanner

**Tia Plautz, United States**

09:00

### SP034.6 - Influences of object size and tube potential pairing on the accuracy of iodine quantification using dual energy CT

**Josh Grimes, United States**

09:15

### SP034.7 - Characterization of Vulnerable Plaque with Dual-Energy during CT Coronary Angiography: A Phantom Study

**Ali Ursani, Canada**

09:30

### SP034.8 - The combination of a custom vascular perfusion contrast agent and dual-energy micro-CT to characterize bone-related vasculature

**Justin Tse, Canada**

09:45

---

**SESSION TIME:** 08:00 – 10:00

**SESSION ROOM:** 718B

**SESSION TRACK:** TRACK 04: RADIATION ONCOLOGY

**SESSION NAME:** SP036 – TREATMENT PLANNING – MOTION AND ROBUSTNESS

**SESSION CHAIR(S):** JAN UNKELBACH, UNITED STATES ALBIN FREDRIKSSON, SWEDEN

### SP036.1 - Robust optimization with independent beams produces robustly matched fields for intensity-modulated proton therapy treatments

**Albin Fredriksson, Sweden**

08:00
08:15  SP036.2 - Rotational tolerance in lung cancer image-guided radiation therapy
        Peter Hoang, Canada

08:30  SP036.3 - Robustness Assessment of a Novel 4D Optimization Approach for Lung Cancer Radiotherapy
        Shahad Al-Ward, Canada

08:45  SP036.4 - The role of VMAT interplay effects for liver stereotactic body radiation therapy
        Gillian Ecclestone, Canada

09:00  SP036.5 - Interplay of MLC, gantry and respiratory motion during DCAT delivery
        Tanya Kairn, Australia

09:15  SP036.6 - Impact of deep inspiration breath hold (DIBH) in lymphoma’s radiation therapy treatment
        Daniel Venencia, Argentina

09:30  SP036.7 - Cardiac sparing in left-sided breast IMRT using robust optimization
        Houra Mahmoudzadeh, Canada

09:45  SP036.8 - Real Time Tumor Position Control During VMAT Hypofractioned Treatment
        Chemseddine Fatnassi, Switzerland

SESSION TIME: 08:00 – 09:45
SESSION ROOM: 716A
SESSION TRACK: TRACK 05: DOSIMETRY AND RADIATION PROTECTION
SESSION NAME: SP037 – DOSIMETRY IN NUCLEAR MEDICINE
SESSION CHAIR(S): ALEXANDRA ZVEREVA, GERMANY

08:00  SP037.1 - Comparative Evaluation of Radiation Dose Rates in Cancer Thyroid Patients Treated with Variable Doses of Radioiodine
        Ajai Kumar Shukla, India

08:15  SP037.2 - Estimation of the influence of other organs of the body in the determination of the gamma fraction energy emitted by iodine 131 deposited within the thyroid gland
        Abderrahim Betka, DZ

08:30  SP037.3 - Personalized compartmental biokinetic modelling and internal dosimetry of two novel radiopharmaceuticals
        Alexandra Zvereva, Germany

08:45  SP037.4 - TLD Measurement of Absorbed Dose of Workers in PET/CT Department
        Pardis Ghafarian, Iran

09:00  SP037.5 - Renewing the radiopharmaceutical accuracy check service for Canadian dose calibrators
        Malcolm McEwen, Canada

09:15  SP037.6 - Radiation Dose Assessment of 99mTc-labeled Tetrofosmin in Patients Undergoing Rest-Stress Myocardial Perfusion Scintigraphy
        Stella Veloza, Colombia

09:30  SP037.8 - Biological Excretion and Half - Life of Remnant Radioactive Iodine 131I in Post Treated Hyperthyroidism Patients.
        Shuaa Al-Sadoon, Jo

SESSION TIME: 08:00 – 09:15
SESSION ROOM: 715B
SESSION TRACK: TRACK 05: DOSIMETRY AND RADIATION PROTECTION
SESSION NAME: SP038 – DOSIMETRY OF NON-STANDARD FIELDS
SESSION CHAIR(S): HUGO BOUCHARD, UNITED KINGDOM
        SJI PAUL, INDIA

08:00  SP038.1 - Determination of small photon field quality correction factors using EBT3 radiochromic film
        Ilias Billas, United Kingdom

08:15  SP038.2 - On the physics of megavoltage small photon field dosimetry
        Hugo Bouchard, United Kingdom

08:30  SP038.3 - Comparison of AAPM TG 148 and UK code of practice of Reference dosimetry in Helical Tomotherapy.
        Siji Paul, India

08:45  SP038.4 - A new facility to support the adaptation of reference dosimetry in the presence of strong magnetic fields
        Simon Duane, United Kingdom

09:00  SP038.5 - The use of ionization chambers and Gafchromic films to determine the reference absorbed dose rate and output factors in a CyberKnife® unit small radiation fields
        Guerda Massillon-Jl, Mexico

SESSION TIME: 08:00 – 09:45
SESSION ROOM: 716B
SESSION TRACK: TRACK 09: BIOSIGNAL PROCESSING
SESSION NAME: SP039 – ECG
SESSION CHAIR(S): ADRIAN CHAN, CANADA
        PHILIP WARRICK, CANADA

08:00  SP039.1 - Improved T-wave Alternans Detection in ECG Signals
        Guangyi Chen, Canada

08:15  SP039.2 - Electrical Left Atrial Conduction Delay with Focused Transthoracic Electrocardiography in Cardiac Resynchronization Therapy
        Matthias Heinke, Germany
08:30 SP039.3 - Electrical Interatrial to Interventricular Conduction Delay Ratio with Focused Transesophageal Electrocardiography in Cardiac Resynchronization Therapy
Matthias Heinke, Germany

08:45 SP039.4 - Analytical geometry based parameters for studying repolarization variability in patients with myocardial infarction
Muhammad Hasan, Canada

09:00 SP039.5 - Acute Mental Stress Detection via Ultra-short term HRV Analysis
Rossana Castaldo, United Kingdom

09:15 SP039.6 - Classification of Abdominal Fetal Electrocardiogram Recordings using Karhunen-Loève Decomposition
Philip Warrick, Canada

09:30 SP039.7 - Dictionary Learning Algorithms For The Application Of Ventricular Arrhythmia Classification.
Iman Kalaji, Canada

SESSION TIME: 08:00 – 09:30
SESSION ROOM: 715A
SESSION TRACK: TRACK 10: REHABILITATION MEDICINE, SPORTS MEDICINE, REHABILITATION ENGINEERING AND PROSTHETICS
SESSION NAME: SP040 – ERGONOMICS, WEARABLE SENSORS AND VIRTUAL REALITY
SESSION CHAIR(S): MICHELE OLIVER, CANADA

08:00 SP040.1 - KEYNOTE: Working to live: The use of field studies and simulations to make workplaces safer
Michele Oliver, Canada

08:30 SP040.2 - Pitch movement acceleration measures during the practice of virtual games in adolescents with Down syndrome
Paulo Lopes, Brazil

08:45 SP040.3 - Movement Training and Assessment with 3D Virtual Reality for Parkinson’s Disease Patient
Chien-An Chen, Chinese Taipei

09:00 SP040.4 - Arm angle detection in egocentric video of upper extremity tasks
Jirapat Likitlersuang, Canada

09:15 SP040.5 - Development of an image-based calibration technique for use with non-ideal postures in the assessment of kinematics using wearable sensors
Monica Gomez, Canada

SESSION TIME: 08:00 – 09:45
SESSION ROOM: 714A
SESSION TRACK: TRACK 11: NEUROENGINEERING, NEURAL SYSTEMS
SESSION NAME: SP041 – BRAIN COMPUTER/MACHINE INTERFACES
SESSION CHAIR(S): BAO-LIANG LU, PEOPLE’S REPUBLIC OF CHINA

08:00 SP041.1 - Cross-subject and Cross-gender Emotion Classification from EEG
Bao-Liang Lu, People’s Republic of China

08:15 SP041.2 - Comparison of Classification Methods for EEG-based Emotion Recognition
Bao-Liang Lu, People’s Republic of China

08:30 SP041.3 - A Brain Computer Interface (BCI) based on intermittent photic-stimulation using multiple coherence to command detection
Antonio Infantisori, Brazil

08:45 SP041.4 - Volitional modulation of neural activity to control a 2 degree-of-freedom brain-machine interface in a rat model
Martha Garcia, Canada

09:00 SP041.5 - Electroencephalography-Based Off-Line Prediction of Specific Grasping Actions Performed with the Same Hand: Towards Integration of Brain-Computer Interfaces and Functional Electrical Stimulation Therapy
Cesar Marquez-Chin, Canada

09:15 SP041.6 - Wireless Distributed Intracortical Neural Interfacing: A New Approach for Brain Machine Interfaces
Alireza Zabihian, Canada

09:30 SP041.7 - Design and construction of a brain-computer interface for applications in neuro robotics
Alma Méndez Gordillo, Mexico

SESSION TIME: 08:00 – 09:45
SESSION ROOM: 701A
SESSION TRACK: TRACK 16: CLINICAL ENGINEERING, CLINICAL PHYSICS, AND PATIENT SAFETY
SESSION NAME: SP042 – TECHNOLOGY MANAGEMENT PROGRAMMES AND EQUIPMENT MANAGEMENT SYSTEMS
SESSION CHAIR(S): JOHN KILDEA, CANADA, TOM JUDD, UNITED STATES

08:00 SP042.1 - KEYNOTE: Medical device systems Health Technology Management (HTM) strategies and best practices
Tom Judd, United States
08:30  SP042.3 - Development of a scoring system to support medical equipment replacement prioritization using the Analytical Hierarchy Process (AHP)
Paul Prowse, Canada

08:45  SP042.4 - Multi-criteria decision analysis to redesign an Italian Clinical Engineering Service under specific needs and regulation requirements
Irene Lasorsa, Italy

09:00  SP042.5 - Developing a system to support equipment repair versus replacement decision making
Sarah Kelso, Canada

Philip Anyango, Kenya

09:30  SP042.7 - Mathematical Model for Reliable Maintenance of Medical Equipment
Abdelbaset Khalaf, South Africa

08:00  SP043.1 - KEYNOTE: One thousand years of women in science
Monique Frize, Canada

08:30  SP043.2 - Creating the Memories and Celebrating the Legacy of Women in Science and Engineering
Ruby Heap, Canada

08:45  SP043.3 - Women In Bio-Medical Engineering In Kenya
Salome Mwaura, Kenya

09:00  SP043.4 - Physics is a waste of your intelligence
Shada Wadi-Ramahi, Saudi Arabia

09:15  SP043.5 - Medical physics? or how a change in career path becomes a passion
Loredana Marcu, Romania

10:00  SP044.1 - Personal Time-Varying Magnetic Fields Evaluation During Activities in MRI Sites
Giuseppe Acri, Italy

10:45  SP044.2 - ECG Imaging of Ventricular Extrasystoles
Olaf Doessel, Germany

11:00  SP044.3 - Experimental Study on Amplitude Frequency of Acoustic Signal Excited by Coupling Magneto-Acoustic Field
Zhongpeng Liu, People’s Republic of China

11:15  SP044.4 - In vivo electric conductivity values of cervical cancer patients reconstructed with a 3T MR system for improved SAR determination
Edmond Balidemaj, Netherlands

11:30  SP044.5 - Focus Tunable Gel Lens Using Annular Dielectric Elastomer Actuator
Thanh Giang La, Singapore

11:45  SP044.6 - Ultra-low-field MRI for improving spatial accuracy of bioelectric source imaging
Koos Zevenhoven, Finlandia

10:30  SP045.1 - Quantitative accuracy of SPECT imaging with a dedicated cardiac camera: Physical phantom experiments
Amir Pourmoghaddas, Canada

10:45  SP045.2 - The Impact of time of flight algorithm and PSF modeling on standard uptake value in clinical PET/CT imaging
Mohammad Reza Ay, Iran

11:00  SP045.3 - Can Pacemaker and ICD degrade CT-Based Attenuation Corrected cardiac SPECT images?
Mohammad Reza Ay, Iran

11:15  SP045.4 - Impact of Point spread function modeling on tumor quantification in clinical PET/CT imaging
Mohammad Reza Ay, Iran

11:30  SP045.5 - Incidental Thyroid Cancer Identified on 18FDG- PET/CT for Ovarian Cancer Evaluation-Case Study.
Shuaa Al-Sadoon, Jordan

11:45  SP045.6 - Zinc material filter for scatter correction in Tc-99m myocardial SPECT imaging: Heart thorax phantom study
Nazifah Abdullah, Malaysia
### Session 046 - Assessment of Radiotherapy Response

#### Time: 10:30 – 12:00

**Session Room:** 718B  
**Session Track:** TRACK 04: RADIATION ONCOLOGY  
**Session Name:** SP046 – ASSESSMENT OF RADIOTHERAPY RESPONSE  
**Session Chair(s):** Issam El Naqa, Canada  
Sarah Mattonen, Canada  

<table>

### Session 047 - Dose Calculation, Part 2

#### Time: 10:30 – 12:00

**Session Room:** 716A  
**Session Track:** TRACK 05: DOSIMETRY AND RADIATION PROTECTION  
**Session Name:** SP048 – DOSIMETRY OF PROTONS AND HEAVY IONS  
**Session Chair(s):** Heidi Nettelbeck, Germany  
Giulia Arico, Germany

### Session 048 - Nanotechnology in Radiation Therapy and Imaging, Part 1

#### Time: 10:30 – 12:00

**Session Room:** 717B  
**Session Track:** TRACK 06: NEW TECHNOLOGIES IN CANCER RESEARCH AND TREATMENT  
**Session Name:** SP049 – NANOTECHNOLOGY IN RADIATION THERAPY AND IMAGING: PART 1  
**Session Chair(s):** Luc Beauleiu, Canada  
Michael Antosh, United States

**Kirpal Kohli, Canada**  

17:15  SP074.2  -  A mobile terminal to follow-up the evolution of chronic diseases  
**Hector Torres, Cuba**  

17:30  SP074.3  -  Relationship between the tuning characteristics of stimulus frequency otoacoustic emissions and behavioral tests at moderate levels  
**Qin Gong, People's Republic of China**  

17:45  SP074.4  -  An Axon Mimic for Medical Electrode Tests  
**Malcolm Latorre, Sweden**  

18:00  SP074.5  -  Evaluation the Accuracy of Oscillometric Blood Pressure Measurement According to the AAMI SP10  
**Haiyan Xiang, People's Republic of China**  

18:15  SP074.6  -  PEMF effects on chondrocyte cellularity and gene expression of the rat distal femoral metaphyseal articular cartilage.  
**Fernando Sotelo-Barroso, Mexico**  

18:30  SP074.7  -  Classification of responders versus non-responders to TDCS by analyzing voltage between anode and cathode during treatment session  
**Isar Nejadgholi, Canada**  

18:45  SP074.8  -  Matlab toolbox for bioelectric cardiac images analysis  
**Juan Alberto Cruz, Brazil**
18:45 SP076.7 - The stochastic extension of the Linear Quadratic model: Taking into account the uncertainty of radiobiological parameters. 
Moises Saez-Beltran, Spain

17:30 SP077.3 - Dosimetric evaluation of the interplay effect for non-gated VMAT treatment of moving targets with high dose rate FFF beams
Ashley Smith, United States

17:45 SP077.4 - In vivo Image Guided Brachytherapy Verification (IGBV) in high dose rate prostate brachytherapy. Initial Clinical Experience
Ryan Smith, Australia

18:00 SP077.5 - Electronic Portal Imaging Device Dosimetry for IMRT: a Review on Commercially Available Solutions
Omemh Bawazeer, Australia

18:15 SP077.6 - The Nano-X Radiotherapy Machine: Lean Innovation Transforming Global Access to Cancer Care
Paul Keall, Australia

18:30 SP077.7 - Development of an MR and CT compatible non-invasive temperature based optical fiber respiration sensor for use in radiotherapy
Ashley Smith, United States

15:45 SP098.4 - Nature’s Own ‘Smart’ Biological Material to Inspire Next-Generation Biomaterials
Joanna Ng, Australia
16:00  SP098.5 - Vascular endothelial cell adhesion and hemocompatibility of biochemically- and topographically-modified poly(vinyl alcohol)
Evelyn Yim, Singapore

16:15  SP012.1 - Effects of PEMF on Neuroblastoma Cells Previously Exposed to Antidepressants
Teodoro Cordova-Fraga, Mexico

16:30  SP012.2 Porous bio-Sic ceramics from wood: approaching new medical implants
Birgit Glasmacher, Germany

SESSION TIME: 15:00 – 16:30
SESSION ROOM: 716A
SESSION TRACK: TRACK 05: DOSIMETRY AND RADIATION PROTECTION
SESSION NAME: SP099 – SPECIAL SESSION: CURRENT SITUATION OF DOSIMETRY IN RADIOLOGY AND RADIATION PROTECTION
SESSION CHAIR(S): MADAN REHANI, UNITED STATES

Speakers: SP099.1 - Madan Rehani, United States
SP099.2 - Pablo Jimenez, United States
SP099.3 - Joanna Izewska, Austria

SESSION TIME: 15:00 – 16:00
SESSION ROOM: 716B
SESSION TRACK: TRACK 05: DOSIMETRY AND RADIATION PROTECTION
SESSION NAME: SP100 – DOSE OPTIMIZATION: FOCUS ON DRLS
SESSION CHAIR(S): GRAEME WARDLAW, CANADA
JOSEP MARTI-CLIMENT, SPAIN

15:00  SP100.1 - A Contribution to the Establishment of Diagnostic Reference Levels in Computed Tomography in Brazil
Ana Marques Da Silva, Brazil

15:15  SP100.2 - Canada’s Computed Tomography (CT) Survey: Overview and Moving Toward Establishment of DRLs
Graeme Wardlaw, Canada

15:30  SP100.3 - Review UAE Dental Radiology Dosimetry Results for National DRLs Establishment
Fatima Al Kaabi, United Arab Emirates

15:45  SP100.4 - Should restrictions on the patients’ behavior during the radiopharmaceuticals incorporation and after 99mTc bone scans be imposed?
Josep Marti-Climent, Spain

SESSION TIME: 15:00 – 17:00
SESSION ROOM: 715A
SESSION TRACK: TRACK 13: INFORMATICS IN HEALTH CARE AND PUBLIC HEALTH
SESSION NAME: SP102 – CLINICAL INFORMATION SYSTEMS AND DECISION SUPPORT
SESSION CHAIR(S): LEANDRO PECCIA, UNITED KINGDOM
JORGE DOS SANTOS, GREECE

15:00  SP102.1 - A Multi-Attribute Decision Theory Approach to Radiation Dose De-escalation in Oropharyngeal Cancer
Wade Smith, United States

15:15  SP102.2 - Large-scale data of basic patient and treatment characteristics significantly improve predictions for post-radiotherapy dyspnea
Andre Dekker, Netherlands
15:30 SP102.3 - Substituting human MRI-observed tumor length with automated tumor length calculations for prediction model application
Johan Van Soest, Netherlands

15:45 SP102.4 - An Artifact Detection Framework for Clinical Decision Support Systems
Shermeen Nizami, Canada

16:00 SP102.5 - Design and implementation of an IT management system for a Medical Physics Department activity workflows
Massimiliano Paolucci, Italy

16:15 SP102.6 - Differential Feature Space in Mean Shift Clustering for Automated Melanoma Assessment
Javier Eslava, United States

16:30 SP102.7 - Fuzzy-state machine for Triage priority classifier in emergency room
Emmanuel Sánchez Velarde, Mexico

16:45 SP102.8 - An Australian mining boom: development of an Australian radiotherapy datamining network for rapid learning from clinical data to support improved clinical decisions
David Thwaites, Australia

17:00 SP104.1 - Monte Carlo simulation of interventional cardiac scenarios using a newborn hybrid phantom and MCNPX code
Fernanda Cavalcante, Brazil

17:15 SP104.2 - Computed tomography of a beating heart: High resolution simulator for the assessment of motion artifacts during CT scan of the heart
Dov Malonek, Israel

17:30 SP104.3 - Development of Dynamic Anthropomorphic Heart Phantom for Computed tomography
Ali Ursani, Canada

17:45 SP104.4 - Development of a PET/MR/CT Compatible Tumour Motion Phantom
John Patrick, Canada

17:00 SP105.1 - KEYNOTE: Advancing MRI for Non-invasive Physiological and Cellular Imaging
Hai-Ling Margaret Cheng, Canada

17:30 SP105.2 - Detection of Regional Radiation-Induced Lung Injury using Hyperpolarized 129Xe Localized Magnetic Resonance Spectroscopy
Brandon Zanette, Canada

17:42 SP105.3 - Conjugate-Mapped Compressed Sensing: a technique to mitigate the side effects of compressed sensing on MTF
Amr Heikal, Canada

17:54 SP105.4 - Gadolinium Labeled Glycosylated Nanomagnetic Particles as Metabolic Contrast Agents in Molecular Magnetic Resonance Imaging
Nader Riyahi-Alam, Iran

18:06 SP105.5 - Hyperpolarized 129Xe Magnetic Resonance Imaging of a Rat Model of Radiation-Induced Lung Injury Involving Single-Lung Radiation Therapy
Ozkan Doganay, Canada

18:18 SP105.6 - Ultra-short Echo Time (UTE) Magnetic Resonance Imaging of Cortical Bone: An Undersampled Acquisition Study
Yanchun Zhu, People's Republic of China

SESSION TIME: 08:00 – 10:00
SESSION ROOM: 718A
SESSION TRACK: TRACK 01: IMAGING
SESSION NAME: SP115 – CT IMAGE QUALITY AND DOSE OPTIMIZATION
SESSION CHAIR(S): ANA MARIA MARQUES DA SILVA, BRAZIL

08:00 SP115.1 - Towards Image Quality Analysis of Small and Full Field of View Dental Cone Beam CT Systems
Ana Maria Marques Da Silva, Brazil

08:15 SP115.2 - Rapid non-invasive spatially varying HVL measurements for CT sources
Matthew Randazzo, United States

08:30 SP115.3 - Development of a CT protocol management system for automated review of CT scanner protocols
Josh Grimes, United States

08:45 SP115.4 - Evaluation of automatic exposure control systems in computed tomography
Paulo Costa, Brazil

09:00 SP115.5 - Development of a Software for Image Quality Assessment in Computed Tomography using the Catphan500® Phantom
Paulo Costa, Brazil

09:15 SP115.6 - Performance of attenuation-based dynamic CT beam-shaping filtration for elliptical subject geometries in dependence of fan- and projection-angle
Stella Veloza, Colombia

09:30 SP115.7 - A software tool for automated artifact detection in scans of the CT daily water phantom
Josh Grimes, United States

09:45 SP115.8 - Monte Carlo Simulation of X-ray Spectra in Computed Tomography Scanner using GATE
Mohammad Reza Ay, Iran
SESSION TIME: 08:00 – 09:30
SESSION ROOM: 715B
SESSION TRACK: TRACK 05: DOSIMETRY AND RADIATION PROTECTION
SESSION NAME: SP118 – DIAGNOSTIC RADIOLOGY: DOSIMETRY AND QUALITY CONTROL
SESSION CHAIR(S): JAMILA SALEM AL SUWAIDI, UNITED ARAB EMIRATES
                      ARUN KUMAR L S, OMAN

08:00 SP118.1 - Measuring absorbed-dose to cardiac implantable electronic device using OSL.
           Étienne Létourneau, Canada
08:15 SP118.2 - Organ dose estimation in computed tomography based on Monte Carlo simulation
           Camille Adrien, France
08:30 SP118.3 - Comparative study of Average Glandular Doses of three different digital mammography units in three Ministry of Health Hospitals in Oman: An analysis
           Arun Kumar L S, Oman
08:45 SP118.4 - First Data on Quality Control Test done in Diagnostic X-ray facility at Major Public Hospitals in Kathmandu Valley, Nepal.
           Kanchan Adhikari, Nepal
09:00 SP118.5 - Estimation of dose distributions in mammography into a tissue equivalent phantom
           Josilene Santos, Brazil

09:15 SP118.7 - Radiation Dose Assessment for Retrospectively ECG-Gated Coronary Computed Tomography Angiography (CCTA) Examination
           C H Yeong, Malaysia

Muthana Al-Ghazi, United States
09:00 SP124.5 - Evaluation and Adaptation of Medical Physics Practicum for Nicaraguan Students at a Canadian Cancer Centre
Alana Hudson, Canada
09:15 SP124.6 - Coordination of AAPM Educational Courses for Developing Countries with Major International and Regional Organizations of Medical Physicists
Eugene Lief, United States
08:00 SP126.1 - Evaluation of Decomposition Analysis on Multi-Models for Digital Volume Pulse Signal
Sheng-Cheng Huang, Chinese Taipei

08:15 SP126.2 - Discordant alternans in a one-dimensional cable of ischemic heart tissue.
Yunuen Cervantes Espinosa, Mexico

08:30 SP126.3 - A Novel Biomechanical Model of the Left Ventricle for Cardiac Contraction Force Reconstruction Applications
Seyyed Mohammad Hassan Haddad, Canada

08:45 SP126.4 - A simulative model approach of cardiopulmonary interaction
Chuong Ngo, Germany

09:00 SP126.5 - The Development of SIM to Characterize Blood Volumetric Flow Rate and Hemodynamics in Human Coronary Arteries
Iyad Fayssal, Lebanon

09:15 SP126.6 - Determination of Bermang’s Minimal Model parameters for diabetic mice treated with Ibervillea sonora
Rodrigo Sánchez-González, Mexico

09:30 SP126.7 - Investigation of flow and turbulence in carotid artery models of varying compliance using particle image velocimetry
Amanda Dicarlo, Canada

SESSION TIME: 08:00 – 09:30
SESSION ROOM: 713B
SESSION TRACK: PRESIDENT’S CALL
SESSION NAME: SP127 – INFORMATICS IN HEALTH CARE AND PUBLIC HEALTH / BIOSENSOR, NANOTECHNOLOGY, BIOMEMS AND BIOPHOTONICS
SESSION CHAIR(S): RICARDO SILVA, ECUADOR
PETER PENNEFATHER, CANADA

08:00 SP127.1 - A study on the leading cause of immunisation schedule fall up defaulting and early child hood malnutrition sicknesse in developing countries(uganda in particular)rural areas/villages
Waigonda Saad, Uganda

08:15 SP127.2 - From Smart Phones to Smart Health
Ricardo Silva, Ecuador

08:30 SP127.3 - Diagnostic Data: a Manifesto
Peter Pennefather, Canada

08:45 SP127.4 - Comparative analysis of co-expression networks reveals molecular changes during the cancer progression
Pegah Khosravi, Iran

09:00 SP127.5 - Copper Meshed Carbon Black PDMS Electrode for Underwater ECG Monitoring
Justin Bales, United States

09:15 SP127.6 - Smartphone-based Monitoring of Tidal Volume and Respiratory Rate
Bersain Reyes, United States

SESSION TIME: 10:30 – 11:45
SESSION ROOM: 718A
SESSION TRACK: TRACK 01: IMAGING
SESSION NAME: SP128 – MULTIMODALITY IMAGING
SESSION CHAIR(S): ELISA KALLIONIEMI, FINLANDIA

10:30 SP128.1 - Localizing cortical motor representation: A comparative study between navigated transcranial magnetic stimulation, BOLD contrast and arterial spin labeling fMRI
Elisa Kallioniemi, Finlandia

10:45 SP128.2 - Evaluation of probable dementia with Lewy bodies using 123I-IMP brain perfusion SPECT, 123I-MIBG myocardial SPECT and voxel-based MRI morphometry
Naoki Kodama, Japan

11:00 SP128.3 - Targeted all-organic nanovesicles for multimodal PET/CT and optical fluorescence assessment of lymphatic disseminations in gynaecologic cancers: A radio-pharmaceutical kit to prepare parenteral injections for a ‘first-in-woman’ clinical study.
Michael Valic, Canada

11:15 SP128.4 - Generation of 4-Class Attenuation Map for MRI Based Attenuation Correction of PET Data in the Head Area Using a Novel Combination of STE/DIXON-MRI and FCM Clustering
Hamidreza Saligheh Rad, Iran

11:30 SP128.5 - A new low field MRI/gamma detector hybrid system
Andrea Abril, Colombia

SESSION TIME: 10:30 – 12:00
SESSION ROOM: 701B
SESSION TRACK: TRACK 01: IMAGING
SESSION NAME: SP129 – IMAGE QUALITY ASSESSMENT (MAMMOGRAPHY AND OTHER)
SESSION CHAIR(S): JAMES ANHKAH, UNITED KINGDOM
MARÍA-ESTER BRANDAN, MEXICO

10:30 SP129.1 - Kilovoltage-CBCT of a Linear Accelerator as a relative imaging device of a spiral CT scanner - dosimetric results
James Annkah, United Kingdom

10:45 SP129.2 - Overall performance, image quality and dose in CR mammography systems operating in the Mexico public health sector
Maria-Ester Brandan, Mexico

11:00 SP129.3 - A Catphan attachment for three dimensional measurements of the modulation transfer function
Elsayed Ali, Canada
11:15  SP129.4 - Sensitometric analyses of screen-film systems for mammography exams in Brazil  
Luis Magalhaes, Brazil

11:30  SP129.5 - New Line Contrast Figure of Merit for image quality assessment  
Aris Dermitzakis, Greece

11:45  SP129.6 - Assessment of Photostimulable Storage Phosphor Imaging Plates Quality in Computed Radiography  
Bárbara Friedrich, Brazil

SESSION TIME: 10:30 – 12:00  
SESSION ROOM: 718B  
SESSION TRACK: TRACK 04: RADIATION ONCOLOGY  
SESSION NAME: SP130 – TREATMENT PLANNING  
SESSION CHAIR(S): WINNIE LI, CANADA

10:30  SP130.1 - Comprehensive Dosimetric Planning Comparison for Early Stage Non-Small Cell Lung Cancer with SABR: Fixed-Beam IMRT versus VMAT versus Tomotherapy  
Ilma Xhaferllari, Canada

10:45  SP130.2 - Development and Validation of an Open Source Tool for Determining Planning Target Volume Margins in Intracranial Stereotactic Radiotherapy  
Winnie Li, Canada

11:00  SP130.3 - Dosimetric impact of accurately delineating the left anterior descending artery in photon and proton radiotherapy  
Janid Blanco Kiely, United States

11:15  SP130.4 - Objective function surrogates for iterative beam angle selection  
Jan Unkelbach, United States

11:30  SP130.5 - A preliminary study on the effect of modulated photon radiotherapy (XMRT) optimization for prostate cancer treatment planning  
Philip McGeachy, Canada

11:45  SP130.6 - Measuring radiation treatment plan similarity in the cloud  
Jennifer Andrea, Canada

10:30  SP131.1 - Sensitivity of Helical Tomotherapy and Elekta Agility VMAT dose distributions to multileaf collimator motion uncertainties for breast radiation treatment with extensive nodal irradiation  
Eric Vandervoort, Canada

10:45  SP131.2 - Use of Varian Trajectory Log Files for Patient Specific Quality Control of TrueBeam VMAT FFF Treatment Deliveries with Portal Dosimetry and Eclipse  
Michael Fan, Canada

11:00  SP131.3 - Machine Learning Facilitates Failure Mode Analysis and Virtual QA for IMRT  
Gilmer Valdes, United States

11:15  SP131.4 - Dosimetric analysis of respiratory-gated RapidArc with varying gating window times  
Ju Young Song, Republic of Korea

11:30  SP131.5 - Current status of dose-tracking using an integrated commercial system  
Stina Svensson, Sweden

11:45  SP131.6 - Enabling Continuous Quality Improvement in a Rapidly Changing Clinical Environment through a Multi-Year Multi-Centre IMRT QC Program: 3 Year Experience  
Andrea McNiven, Canada

12:00  SP131.7 - A new approach to spatial gradient signal encoding for external beam radiotherapy delivery verification  
Robert Heaton, Canada

10:30-11:30  
SESSION ROOM: 715B  
SESSION TRACK: TRACK 05: DOSIMETRY AND RADIATION PROTECTION  
SESSION NAME: SP132 – SPECIAL SESSION: IMPLEMENTATION OF THE NEW BSS INCLUDING RADIATION SAFETY CULTURE IN MEDICINE  
SESSION CHAIR(S): MADAN REHANI, UNITED STATES

Speaker: SP132.1 - Madan Rehani, United States

Speaker: SP132.2 - Ola Holmberg, Austria

Speaker: SP132.3 - Pablo Jimenez, United States

10:30 SP134.1 - Impedance and comfort of dry multipin electrodes for electroencephalography  
*Patrique Fiedler, Germany*

10:45 SP134.2 - Wearable Gait Analysis using Vision-aided Inertial Sensor Fusion  
*Eric Ma, Canada*

11:00 SP134.3 - Two-Vector Capacitive Electrocardiogram Measurement Using Three Fabric Electrodes for Automobile Application  
*Shunsuke Takayama, Japan*

11:15 SP134.5 - Detection of REM Behaviour Disorder Based on Low-Power Compressive Sensing of EMG  
*Sridhar Krishnan, Canada*

11:30 SP134.6 - Externally applied pressure on the skin electrode impedance  
*Bahareh Taji, Canada*
10:30 Opening Remarks
Slavik Tabakov, United Kingdom
Fridtjof Nuesslin, Germany

10:40 SP137.1 - Cost-Effective Provision of Medical Physics and Medical Engineering Services in Healthcare
Peter H S Smith, United Kingdom

10:50 SP137.2 - Implementing Training Modules of the Emerald Program in Brazil
Ricardo Terini, Brazil

11:00 SP137.3 - Pilot Implementation In The Philippines Of Structured Medical Physics Residency Programs Using The Iaea Training Guides For The Clinical Training Of Medical Physicists
Agnette Peralta, Republic of the Philippines

11:10 SP137.4 - Capacity Building of Medical Physics in Bangladesh
Hasin Anupama Azhari, Bangladesh

11:20 SP137.5 - Education & Training of Medical Physics in Africa: Challenges & Opportunities
Ahmed IbnSeddick

11:30 SP137.6 - Retention of trained medical physicists in African states: Do our Governments have a role to play
Rebecca Nakatudde

11:40 SP137.7 - Strengthening Medical Physics Clinical Competencies in a Challenging Environment - Update on the IAEA Supported Nigerian (NIR/6/023) Project
Taofeeq Ige, Nigeria

11:50 SP137.8 - Capacity Building of Medical Physics in Ghana and Africa
Stephen Inkoom, Ghana
16:00 SP139.5 - Development of Polymer Substrates for Waveguide Evanescent Field Fluorescence Microscopy  
*Rony Sharon, Canada*

16:15 SP139.6 - Higher-Order Structural Investigation of Mammalian Septins by Super-Resolution Fluorescence Microscopy
*Adriano Vissa, Canada*

---

15:00 SP140.1 - Credentialing of radiotherapy centres in Australasia for a phase III clinical trial on SABR  
*Tomas Kron, Australia*

15:15 SP140.2 - LED-optimized SBRT for Peripheral Early Stage Lung Cancer: A technique to reduce lung dose and potentially allow for re-irradiation  
*Brandon Disher, Canada*

15:30 SP140.3 - Delivery of VMAT treatments with nonstandard SAD using dynamic trajectories  
*Joel Mullins, Canada*

15:45 SP140.4 - Cone-Beam CT assessment of inter-fraction and intra-fraction motions during lung stereotactic body radiotherapy with and without abdominal compression  
*Ruqing Jiang, Canada*

16:00 SP140.5 - Initial experience in establishing frameless intra-cranial stereotactic radiosurgery program with Varian TrueBeam STx, 6DoF couch and VisionRT motion control system  
*Sergei Zavgorodni, Canada*

---

15:00 SP141.1 - Theoretical description of the saturation correction of ionization chambers in pulsed fields with arbitrary repetition rate  
*Leonhard Karsch, Germany*

15:15 SP141.2 - Performance characteristics of Gafchromic EBT3 film in therapeutic electron beams and its practical application as an in-vivo dosimeter in the clinic  
*Amanda Barry, Ireland*

15:30 SP141.3 - Photon and electron spectra inside small field detectors for narrow and broad 6 MV photon beams  
*Hamza Benmakhlfou, Sweden*

15:45 SP141.4 - Real Time Dose Reconstruction in MV Photon Therapy using a 2D solid state detector array.  
*Michael Lerch, Australia*

16:00 SP141.5 - Energy Correction factor for Plane Parallel ion-chamber and its Use in Clinical photon Beam Dosimetry  
*Kamlesh Passi, India*

---

15:00 SP142.1 - Proton Minibeam Radiation Therapy (pMBRT): implementation at a clinical center  
*Yolanda Prezado, France*

15:15 SP142.2 - Hadron minibeam radiation therapy: feasibility study at Heidelberg Ion Therapy Center  
*Yolanda Prezado, France*

15:30 SP142.3 - Acoustic Range Verification of Proton Beams: Simulation Assessment of the Challenges of Clinical Application  
*Kevin Jones, United States*

15:45 SP142.4 - Radiochromic Film Based Dose Calibration and Monitoring for Radiobiological Experiments using Low Energy Proton Beams  
*Belal Moftah, Saudi Arabia*

16:00 SP142.5 - Development of 3D measurement device dedicated for range-compensator QA  
*Shigekazu Fukuda, Japan*

Bruce Curran, United States

15:30  SP147.2 - AIM Quality Assurance Program Development for CT X-Ray Systems
Douglas McTaggart, Canada

15:45  SP147.3 - Evaluation of Improved Automatic Speech Recognition Prototype for Estonian Language in Radiology Domain
Andrus Paats, Estonia

16:00  SP147.4 - Usability engineering approach towards secure open networks in the integrated operating room of the future
Klaus Radermacher, Germany

16:15  SP147.5 - Whiteboard ESB: Next Generation Data and Workflow Management for Radiation Oncology
John Wolfgang, United States

SESSION TIME:  17:00 – 18:45
SESSION ROOM:  718A
SESSION TRACK:  TRACK 01: IMAGING
SESSION NAME:  SP149 – ITERATIVE RECONSTRUCTION
SESSION CHAIR(S):  IDRIS ELBAKRI, CANADA  DMITRI MATENINE, CANADA

17:00  SP149.1 - Preliminary study on reduction of cartoon artifact in the iteratively reconstructed images from sparse projection views
Sunhee Wi, Republic of Korea

17:15  SP149.2 - Evaluation of the OSC-TV Reconstruction Algorithm for Optical Cone-Beam Computed Tomography
Dmitri Matenine, Canada

17:30  SP149.3 - Subjective low contrast performance of four CT scanners with iterative reconstruction
Azeez Omotayo, Canada

17:45  SP149.5 - Sparse-view image reconstruction with compressed sensing and its application in low dose CT myocardial perfusion imaging
Esmaeil Enjilela, Canada

18:00  SP149.6 - Feasibility study for 3D cone-beam computed tomography reconstruction with few projection data using MLEM algorithm with total variation minimization
Dong Hoon Lee, Republic of Korea

18:15  SP149.7 - A weighted stochastic gradient descent algorithm for image reconstruction in 3D computed tomography
Davood Karimi, Canada

18:30  SP149.8 - Investigation of sparse-angle view in cone beam computed tomography (CBCT) reconstruction algorithm using a sinogram interpolation method
Dohyeon Kim, Republic of Korea

15:15  SP148.2 - Ways to outreach medical devices in low resource countries (LRC)
K Siddique Rabbani, Bangladesh

15:30  SP148.3 - South African-Swedish effort on pre-hospital diagnostics of stroke and traumatic injuries
Mikael Persson, Sweden

15:45  SP148.4 - A portable multi-frequency impedance measuring device for biodynamic analysis
Takao Nakamura, Japan

16:00  SP148.5 - A Study of the Challenges of Donating Medical Equipment to Developing Countries
Bill Gentles, Canada

16:15  SP148.6 - The Clinicopathologic Characters and Activity Survey of Sudden Death of Infant in a Depressed Economy: South-Eastern Nigeria Experience.
Gideon Ndubuka, Nigeria

Priyajit Ghosh, India
SESSION TIME: 17:00 – 18:45
SESSION ROOM: 701B
SESSION TRACK: TRACK 01: IMAGING
SESSION NAME: SP150 – X-RAY PHASE CONTRAST & SCATTER IMAGING
SESSION CHAIR(S): PAUL JOHNS, CANADA
RHIANNON MURRIE, AUSTRALIA

17:00 SP150.1 - Reducing signal extraction artefacts for x-ray scatter imaging with multiple pencil beams
Paul Johns, Canada

17:15 SP150.2 - Live animal phase contrast x-ray velocimetry of the lungs: Optimising imaging speed for synchrotron and lab source imaging
Rhiannon Murrie, Australia

17:30 SP150.3 - X-ray Phase-Contrast imaging: from mammography to breast tomodraphy using synchrotron radiation
Renata Longo, Italy

17:45 SP150.4 - 4 Years of X-ray Imaging at 05B1-1 Beamline at BMIT
Tomasz Wysokinski, Canada

18:00 SP150.5 - An energy dispersive bent Laue monochromator for K-edge subtraction imaging
Nazanin Samadi, Canada

18:15 SP150.6 - An incoherent implementation of x-ray phase contrast imaging and tomodraphy that maintains high sensitivity at low delivered doses
Alessandro Olivo, United Kingdom

18:30 SP150.7 - Indirect measurement of average alveolar size using dynamic phase-contrast imaging
Mercedes Martinson, Canada

SESSION TIME: 17:00 – 19:00
SESSION ROOM: 714B
SESSION TRACK: TRACK 03: BIOMECHANICS AND ARTIFICIAL ORGANS
SESSION NAME: SP151 - CARDIO MECHANICS & ORGANS
SESSION CHAIR(S): DAVID MACKU, CZECH REPUBLIC

17:00 SP151.1 - KEYNOTE: Biomechanics and artificial organs
Birgit Glasmacher, Germany

17:30 SP151.2 - The Continuous Flow Total Artificial Heart in Clinical Practice
David Macku, Czech Republic

17:45 SP151.3 - Power Control Range of Operation for the Left Ventricular Assist Device in Bridge-to-Recovery Treatment
Marwan Simaan, United States

18:00 SP151.4 - An quantitative estimation method of peripheral perfusion by using a CCD camera during rotary blood pump support
Yasuyuki Shiraishi, Japan

18:15 SP151.5 - Mathematical Modeling of Left Ventricle Stroke Work Following Transcatheter Aortic Valve Replacement Associated With Paravalvular Leaks
Azadeh Saeedi, Canada

18:30 SP151.6 - Criteria to study Heart Failure derived from ESPVR
Rachid Shoucri, Canada

18:45 SP151.7 - Fluid Dynamics of Transcatheter Aortic Valve Associated with Paravalvular Leak
Azadeh Saeedi, Canada

SESSION TIME: 17:00 – 18:30
SESSION ROOM: 718B
SESSION TRACK: TRACK 04: RADIATION ONCOLOGY
SESSION NAME: SP152 – SPECIAL TREATMENT TECHNIQUES: PART 2
SESSION CHAIR(S): EMILY HEATH, CANADA
CHARLES SHANG, UNITED STATES

17:00 SP152.1 - Optimal timing in concomitant chemotherapy and radiation therapy of colorectal tumors in nude mouse treated with Cisplatin and LipoplatinTM
Thititip Tippayamontri, Canada

17:15 SP152.2 - Grid therapy: impact of radiobiological models on calculation of therapeutic ratio
Hassan Ali Nedaie, Iran

17:30 SP152.3 - Will CyberKnife M6? Multileaf collimator offer advantages over IRIS? collimator in prostate SBRT?
Charles Shang, United States

17:45 SP152.4 - Retrospective analysis of treatment margins for stereotactic ablative lung cancer treatments based on 4D CBCT
Sheeba Thengumpallil, Switzerland

18:00 SP152.5 - Using surgical clips in the tracking of liver tumors applied to CyberKnife SBRT treatments
Leonie Petitclerc, Canada

18:15 SP152.6 - A Novel Couch-Gantry Trajectory Based Stereotactic Treatment Method
Byron Wilson, Canada

17:00 SP154.1 - Biomechanics and artificial organs
Birgit Glasmacher, Germany

17:30 SP154.2 - The Continuous Flow Total Artificial Heart in Clinical Practice
David Macku, Czech Republic

17:45 SP154.3 - Power Control Range of Operation for the Left Ventricular Assist Device in Bridge-to-Recovery Treatment
Marwan Simaan, United States

18:00 SP154.4 - An quantitative estimation method of peripheral perfusion by using a CCD camera during rotary blood pump support
Yasuyuki Shiraishi, Japan

18:15 SP154.5 - Mathematical Modeling of Left Ventricle Stroke Work Following Transcatheter Aortic Valve Replacement Associated With Paravalvular Leaks
Azadeh Saeedi, Canada

18:30 SP154.6 - Criteria to study Heart Failure derived from ESPVR
Rachid Shoucri, Canada

18:45 SP154.7 - Fluid Dynamics of Transcatheter Aortic Valve Associated with Paravalvular Leak
Azadeh Saeedi, Canada
SESSION TIME: 17:00 – 18:45
SESSION ROOM: 701A
SESSION TRACK: TRACK 04: RADIATION ONCOLOGY
SESSION NAME: SP153 – QUALITY ASSURANCE: PART 4
SESSION CHAIR(S): YOUNG LEE, CANADA
DAVID THWAITES, AUSTRALIA

17:00 SP153.1 - Comparison of AAA and CCC Algorithms for H&N RapidArc pre-patient treatment QA
Thuso Ramaloko, South Africa

17:15 SP153.2 - Tuning treatment planning system model parameters for accurate VMAT dose calculation using conformal arc plans
Orest Ostapiak, Canada

17:30 SP153.3 - Prostate brachytherapy with Oncentra Seeds: Intra-operative planning and delivery software validation assisted by an FMEA
Renee Larouche, Canada

17:45 SP153.4 - Investigation of predictive parameters for pre-treatment measurement pass rates in hypofractionated volumetric arc therapy (HF-VMAT) plans of single brain metastasis
Young Lee, Canada

18:00 SP153.5 - Inter-centre comparison of dose delivery accuracy for six different linac-planning system combinations for SBRT lung cancer treatment using FFF beams.
David Thwaites, Australia

18:15 SP153.6 - A pilot study investigating the impact of treatment delivery uncertainties for lung SABR using step and shoot IMRT and VMAT
David Thwaites, Australia

18:30 SP153.7 - Adaptive patient dose assessment using daily 3D cone beam CTs and Monte Carlo simulations
Nevin McVicar, Canada

17:30 SP154.1 - Ferrous - methylthymol blue - gelatin gel dosimeter with improved auto-oxidation stability
Kalim Penev, Canada

17:45 SP154.2 - The dosimetric property of TLD2000 thermoluminescent dosimeter
Nan Zhao, People’s Republic of China

18:00 SP154.5 - Aligning the ALARA principle with FFF treatment modalities
Stephen Sawchuk, Canada

18:15 SP154.6 - Reduction of residual signal in LiF:Mg, Cu, P thermoluminescent material.
Vinod Nelson, Australia

18:30 SP154.7 - Application of dose gels in HDR brachytherapy
Diana Adliene, Lithuania

18:45 SP154.8 - Practical 3D QA for Radiation Therapy Based on High-Resolution Laser CT of Reusable Radiochromic Polymer-Gel Dosimeters in Dedicated Phantoms
Stephen Avery, United States

17:00 SP159.1 - KEYNOTE: Dwarfing Big Data for Oncology Applications: Necessity and Possibilities
Issam El Naqa, Canada

17:30 SP159.2 - Improved temperature monitoring and treatment planning for loco-regional hyperthermia treatments of Non-Muscle Invasive Bladder Cancer (NMIBC)
Gerben Schooneveldt, Netherlands

17:45 SP159.3 - A Full 3D CFD Model Coupled with an Outflow Lumped Boundary and Inflow Total Pressure Formulation to Estimate Human Cardiac Perfusion
Iyad Fayssal, Lebanon

18:00 SP159.4 - Simulation Model of Image-Guided Percutaneous Thermal Ablation in the Assessment of Optimal Approach for Complete Tumour Ablation
Chai Hong Yeong, Malaysia

17:00 SP160.1 - From 'Fracking' and 'Macrovoids' to the Onset of Cancer Metastasis: A Mechano-Metabolomics Model of a Plausible Fluid-Solid Network Instability in Tumors
Sai Prakash, United States

17:15 SP160.2 - Surface electromyography in quantifying Parkinson's disease and its treatment with deep brain stimulation
Pasi Karjalainen, Finlandia

17:30 SP160.3 - A Decade of Experience with Intraoperative Microelectrode Recording in Determining the Subthalamic Nuclie (STN) Deep Brain Stimulation? Lead Positions in 260 Parkinson Diseased Conditions in South India? A Retrospective Study
Venkateshwarla Raju, India

17:45 SP160.4 - Vortex of the Magnetic Field on the Growth Rate of Escherichia Coli
Teodoro Cordova - Fraga, Mexico

18:00 SP160.5 - Electro Magnetic Therapy and Laser in the Chronic Pain Of The Woman
Manuel Zuniga, Ecuador
Friday, June 12 2015

SESSION TIME: 08:00 – 09:45
SESSION ROOM: 718A
SESSION TRACK: TRACK 01: IMAGING
SESSION NAME: SP161 – ANGIOGRAPHY / X-RAY IMAGING
SESSION CHAIR(S): JOSÉ CARLOS DE LA VEGA, CANADA
JEFF FRIMETH, CANADA

08:00 SP161.1 - 5D DSA Using Dual Energy Acquisition
Gabe Shaughnessy, United States

08:15 SP161.2 - Investigation of Rhenium-Doped Microsphere-Based Contrast Agents for Diagnostic X-Ray Imaging
José Carlos De La Vega, Canada

08:45 SP161.3 - Theoretical and experimental comparison of image signal and noise for dual-energy subtraction angiography and conventional x-ray angiography
Christiane Burton, Canada

09:00 SP161.4 - Some Physical and Clinical Factors Influencing the Measurement of Precision Error, Least Significant Change, and Bone Mineral Density in Dual-Energy X-Ray Absorptiometry
Jeff Frimeth, Canada

09:15 SP161.5 - Use of Conventional Regional DXA Scans for Estimating Whole Body Composition
Mohammad Reza Salamat, Iran

09:30 SP161.6 - Multiple Energy Synchrotron Biomedical Imaging System? Preliminary Results
Bassey Bassey, Canada

SESSION TIME: 08:00 – 10:00
SESSION ROOM: 716A
SESSION TRACK: TRACK 05: DOSIMETRY AND RADIATION PROTECTION
SESSION NAME: SP163 – PRIMARY DOSIMETRY STANDARDS
SESSION CHAIR(S): NATALKA SUCHOWERSKA, AUSTRALIA
RONALD TOSH, UNITED STATES

08:00 SP163.1 - KEYNOTE: Candidate Technologies for Next-Generation Dosimetry Standards
Ronald Tosh, United States

08:30 SP163.2 - Absorbed dose to water measurements in a clinical carbon ion beam using water calorimetry
Julia-Maria Osinga, Germany

08:45 SP163.3 - Results from the on-going key comparison BIPM.RI(I)-K6 : What have we learned?
Susanne Picard, France

09:00 SP163.4 - Absorbed dose-to-water primary standard and traceability system for radiotherapy in China
Kun Wang, People’s Republic of China

08:00 SP161.2 - To tap or not to tap: A comparison of cranial 3D to 2D ultrasound in extremely preterm neonates with post-hemorrhagic ventricle dilation to predict the necessity of interventional ventricular tap
Jessica Kishimoto, Canada

08:30 SP161.3 - Endoleak and Thrombus Characterization with Dynamic Elastography after Endoleak Embolization following Aneurysm Endovascular Repair
Antony Bertrand-Grenier, Canada

08:45 SP161.4 - Detecting lipid-rich artery plaque using a handheld photoacoustic imaging device
Susumu Hirano, Japan

09:00 SP161.5 - Intersex differences in posterior eye chamber by spectral optical coherent tomography
Zofia Drzazga, Poland

09:15 SP161.6 - Longitudinal Analysis of 3D Pre-Term Neonatal Ventricle Ultrasound Images
Wu Qiu, Canada

09:30 SP161.7 - Breast Invasive Ductal Carcinoma Assessed by Conventional Ultrasound and Contrast-Enhanced Ultrasound in Different T-Stages
Yanchun Zhu, People’s Republic of China

09:45 SP161.8 - Comparison of ultrasound systems in scoliosis measurement
Maggie Hess, Canada

08:00 SP162.1 - Endoluminal Ultrasound Biomicroscopy for in vivo detection of caustic esophagitis in rats
João Machado, Brazil
09:30  SP163.5 - Design of an MRI-compatible water calorimeter for use in an integrated MRI-Linac and Gamma-Knife
        Niloufar Entezari, Canada

09:45  SP163.6 - On the practical use of calorimetry for routine absolute dosimetry in the radiotherapy clinic
        James Renaud, Canada

SESSION TIME: 08:00 – 09:45
SESSION ROOM: 718B
SESSION TRACK: TRACK 06: NEW TECHNOLOGIES IN CANCER RESEARCH AND TREATMENT
SESSION NAME: SP164 – ADAPTIVE RADIATION THERAPY (ART)
SESSION CHAIR(S): EVA BEZAK, AUSTRALIA
                   DANIEL TAMAGI, CANADA

08:00  SP164.1 - Real-time dose reconstruction for adaptive radiation therapy
        Martin Fast, United Kingdom

08:15  SP164.2 - Evaluation of unified intensity-modulated arc therapy (UIMAT) for the treatment of head-and-neck cancer
        Michael Macfarlane, Canada

08:30  SP164.3 - A Hybrid IMRT/VMAT Technique for the Treatment of Nasopharyngeal Cancer
        Nan Zhao, People’s Republic of China

08:45  SP164.4 - Interactive real time adaptation of IMRT treatment plans
        Cornelis Philippus Kamerling, United Kingdom

09:00  SP164.5 - A Hybrid IMRT/VMAT technique for the treatment of non-small cell lung cancer
        Nan Zhao, People’s Republic of China

09:15  SP164.6 - Offline adaptive VMAT - feasibility study using planning CT deformed electron density mapping on daily CBCT to estimate parotid dose volume relationship
        Vellian Subramani, India

09:30  SP164.7 - Plan Optimization for a Lung Patient on a Parallel Linac-MR System
        Daniel Tamagi, Canada

SESSION TIME: 08:00 – 10:00
SESSION ROOM: 714B
SESSION TRACK: TRACK 11: NEUROENGINEERING, NEURAL SYSTEMS
SESSION NAME: SP166 – NEUROPROSTHESES
SESSION CHAIR(S): PAUL YOO, CANADA

08:00  SP166.1 - Enhanced Transcutaneous Electrical Nerve Stimulation (eTENS): A Novel Method of Achieving Posterior Tibial Nerve Stimulation Therapy for Overactive Bladder
        Paul Yoo, Canada

08:15  SP166.2 - Decreasing Upper Extremity Demands During Sitting Pivot Transfers for Individuals with Spinal Cord Injury by Utilizing Functional Electrical Stimulation
        Stephanie Bailey, United States

08:30  SP166.3 - Design of Orthotic Mechanisms to Control Stand-to-Sit Maneuver for Individuals with Paraplegia
        Ronald Triolo, United States

08:45  SP166.4 - Improved Peripheral Nerve Recording with a Small Form-Factor Nerve Cuff Electrode: A Computational Study
        Parisa Sabetian, Canada

09:00  SP166.5 - Effect of stimulation on non-erect postures with a standing neuroprosthesis
        Brooke Odle, United States

09:15  SP166.6 - Automatic Detection of Destabilizing Wheelchair Conditions for Modulating Actions of Neuroprostheses to Maintain Seated Posture
        Ronald Triolo, United States

09:30  SP166.7 - Selecting Upper Extremity Command Signals to Modulate Electrical Stimulation of Trunk Muscles during Manual Wheelchair Propulsion
        Stephanie Bailey, United States

SESSION TIME: 08:00 – 09:15
SESSION ROOM: 718B
SESSION TRACK: TRACK 09: BIOSIGNAL PROCESSING
SESSION NAME: SP165 – EEG
SESSION CHAIR(S): JENS HAUIEWSN, GERMANY
                   TEODIANO BASTOS-FILHO, BRAZIL

08:00  SP165.1 - A Fully Unsupervised Clustering on Adaptively Segmented Long-term EEG Data
        Vaclav Gerla, Czech Republic

08:15  SP165.2 - A Real-Time Clustered MUSIC algorithm for the localization of synchronous MEG/EEG source activity
        Daniel Baumgarten, Germany

08:30  SP165.3 - Spatial harmonics for compressive sensing in electroencephalography
        Jens Hauiesen, Germany

08:45  SP165.4 - An Evaluation of Performance for an Independent SSVEP-BCI Based on Compression Sensing System
        Teodiano Bastos-Filho, Brazil

09:00  SP165.5 - Multi-way based Source Localization of Multichannel EEG signals Exploiting Hilbert-Huang Transform
        Saeed Pouryazdian, Canada
SESSION TIME: 08:00 – 09:45
SESSION ROOM: 717B
SESSION TRACK: TRACK 13: INFORMATICS IN HEALTH CARE AND PUBLIC HEALTH
SESSION NAME: SP169 – SELF ENGAGEMENT, PATIENT EMPOWERMENT AND MHEALTH
SESSION CHAIR(S): GIUSEPPE FICO, SPAIN ELENI KALDOUDI, GREECE

08:00  SP169.1 - KEYNOTE: Empowering patients through information technologies
       Eleni Kaldoudi, Greece

08:30  SP169.2 - Distributed learning: developing a predictive model for dyspnea in lung cancer patients based on data from multiple hospitals
       Johan Van Soest, Netherlands

08:45  SP169.3 - User Centered Design to incorporate predictive models for Type 2 Diabetes screening and management into professional decision support tools: preliminary results.
       Giuseppe Fico, Spain

09:00  SP169.4 - Quantifying Bipolar Disorder for Technology-Assisted Self-Management
       James Amor, United Kingdom

09:15  SP169.5 - Hippocratic Protocol Design to Improve Security and Privacy in Healthcare Applications for NFC Smartphone
       Jose Pirrone Puma, Venezuela

09:30  SP169.6 - Extracting Intention from Web Queries? Application in eHealth Personalization
       George Drosatos, Greece

Sara Mahallati, Canada

10:45 SP178.2 - Astrocytes enhance neuronal long term potentiation in a biophysical model of epilepsy
Vasily Grigorovsky, Canada

11:00 SP178.3 - Influence of the ‘sympathetic slump’ on biomechanics of the sympathetic trunk
Liesbeth Van Hauwermeiren, Belgium

11:15 SP178.4 - Superparamagnetic Nanoparticles for Epilepsy Detection
Ebrahim Ghafar-Zadeh, Canada

11:30 SP178.5 - Automatic detection of epileptic seizures in scalp EEG
Yasser Pérez, Cuba

11:45 SP178.6 - Beta/Theta Neurofeedback Training Effects in Physical Balance of Healthy People
Wenya Nan, People's Republic of China

12:00 SP178.7 - Potential Benefits in Comparing the Neural Control Networks Studies Between the Oculomotor and Cardiac Pacing Systems
Michael Cheng, Canada

10:30 SP179.1 - Acceptance Test of the first Hospital Cyclotron for Production of PET tracers in Iran
Pardis Ghafarian, Iran

10:45 SP179.2 - HiFEM - An Integrated Approach for Human Centered Risk Management for Medical Devices
Klaus Radermacher, Germany

11:00 SP179.3 - Ultrasonic Microscanning for Digital Dental Impressioning
Klaus Radermacher, Germany

11:15 SP179.4 - A study on prefrontal blood flow in patients with moderate dementia and severe dementia using near-infrared
Shingo Takahashi, Japan

SESSION TIME: 10:30 – 11:30
SESSION ROOM: 715B
SESSION TRACK: TRACK 12: MEDICAL DEVICES
SESSION NAME: SP179 – MEDICAL DEVICES: MISCELLANEOUS
SESSION CHAIR(S): KLAUS RADERMACHER, GERMANY

10:30 SP180.1 - Increasing efficiency of data transfer in WBANs
Luka Celic, Croatia

10:45 SP180.2 - Decision support system for no common emergency in a big city with intelligent routing algorithm and attention quality parameters evaluation.
Lupe Toscano, Peru

11:00 SP180.3 - Development of a Multi-Center Clinical Trial Data Archiving and Analysis Platform
Brandon Driscoll, Canada

11:15 SP180.4 - Global Health Catalyst: A systematic Space-time compression platform for catalyzing global health collaborations in Radiation Oncology
Wilfred Ngwa, United States
The IUPESM 2015 Posters will be displayed in the Exhibit Hall during open hours.

Presenting Author Stand By Time: Presenters are requested to stand by their posters during the networking breaks scheduled 10:00 - 10:30 and 16:30 - 17:00 Monday, June 8 to Thursday, June 11.

**PS01 – TRACK 01: IMAGING**

**PS01.001** – A discontinuity artefact at the isocenter of on-board CBCT images
Elsayed Ali, Canada

**PS01.002** – Correction of Metal Artefacts Induced from Pacemaker and ICD Leads in CT-Based Attenuation Correction of Cardiac SPECT data
Mohammad Reza Ay, Iran

**PS01.003** – Anthropomorphic Phantom of the Pancreas for Scintillation Camera Tests
Lourdes Brasil, Brazil

**PS01.004** – Comparing two image processing techniques, Wavelet and Segmentation by threshold, for detecting microcalcifications in an image mammographic.
Lourdes Brasil, Brazil

**PS01.005** – Measuring red blood cell velocity in capillary using video and image processing
Surapong Chatpun, Thailand

**PS01.006** – Development of a Quantitative PET QA Procedure for Multi-Center Clinical Trials
Brandon Driscoll, Canada

**PS01.007** – Unwrapping highly wrapped phase using Nonlinear Multi-Echo phase unwrapping
Chemseddine Fatnassi, Switzerland

**PS01.008** – Investigation of optimal display size for viewing MRI images using a digital contrast-detail phantom
Hideki Fujita, Japan

**PS01.009** – Investigation of presampled MTF using a slit device with slightly wider aperture
Rumi Gotanda, Japan

**PS01.010** – 3D Tumor delineation in Positron Emission Tomography reconstructed images restored by the use of Lucy Richardson blind deconvolution method
Albert Guvenis, Turkey

**PS01.011** – Different options for stimulation intensity in mapping cortical motor area in navigated transcranial magnetic stimulation
Petro Julkunen, Finland

**PS01.012** – Software Breast Phantom for Phase Contrast Imaging Applications
Nicolas Pallikarakis, Greece

**PS01.013** – Actions for Implementation Program of Image Quality of Mammography
Ana Cláudia Patrocinio, Brazil

**PS01.014** – Evaluating Techniques of Transformation Intensity for Contrast Enhancement in Mammographic Images
Ana Cláudia Patrocinio, Brazil

**PS01.015** – Influence of Contrast Enhancement to Breast Density Classification by Using Sigmoid Function
Ana Cláudia Patrocinio, Brazil

**PS01.016** – Evaluation of the difficulties of the learning process of mammographic readings
Ana Cláudia Patrocinio, Brazil

**PS01.017** – Non-deterministic optimization using Differential Evolution algorithm to launch seeds for liver segmentation in MDCT
Ana Cláudia Patrocinio, Brazil

**PS01.018** – Influence of ROI pattern on segmentation in lung lesions
Ana Cláudia Patrocinio, Brazil

**PS01.019** – Comparison between Elliptical and Squared ROI to Launch an Automatic Seed to Region Growing Algorithm on Hepatic Segmentation using CT images
Ana Cláudia Patrocinio, Brazil

**PS01.020** – Gd-based Nanoparticles Mediated Magnetic Field Enhancement Inside Homogenous Tissue: Simulation using Finite Element Method
Nader Riyahi-Alama, Iran

**PS01.021** – Novel Cylindrical Source Tank for Inserts of Emission Computed Tomography Phantoms
Inayatullah Sayed, Malaysia

**PS01.022** – Linear tomosynthesis with flat-panel detector for image guided radiation therapy
Tae-Suk Suh, Republic of Korea

**PS01.023** – Evaluation of image quality and dose for digital breast tomosynthesis (DBT) using a semi-analytical model
Alessandra Tomal, Brazil

**PS01.024** – Optimization of acquisition parameters of the test of an overall SPECT/CT system performance.
Piotr Tulik, Poland

**PS01.025** – Dosimetric Analysis of Patient to a Z-Gradient Coil in Head Magnetic Resonance Imaging
Shoogo Ueno, Japan

**PS01.026** – A Novel Optical System for Contrast Enhancement in Histological Plates to Be Processed Digitally
Rubiel Vargas-Canas, Colombia

**PS01.027** – Pixel-based dynamic contrast-enhanced CT study with low temporal resolution
Ivan Yeung, Canada
PS02 – TRACK 02: BIOMATERIALS AND REGENERATIVE MEDICINE

PS02.001 – Chitosan: A Chitinous Biopolymer For The Treatment Of Crude Oil Polluted Water
Eileen Agoha, Nigeria

PS02.002 – Temperature of ice formation affects integrity of alginate 3D constructs after cryopreservation
Birgit Glasmacher, Germany

PS02.003 – Influence of proteins on magnesium in vitro degradation
Birgit Glasmacher, Germany

PS02.004 – Electrospinning of vascular prostheses with anti-kinking properties
Birgit Glasmacher, Germany

PS02.005 – Electrospinning of polycaprolactone/chitosan polymeric fibrous membranes as scaffolds for cardiovascular tissue engineering applications
Birgit Glasmacher, Germany

PS02.006 – Coaxial electrospinning of piezoelectric PVDF/PCL scaffolds for nerve regeneration
Birgit Glasmacher, Germany

PS02.007 – Bio rapid prototyping project: Evaluation of spheroid formation for cells construct
Takeshi Shimoto, Japan

PS02.008 – Scaffold Prototype for Heart Valve Tissue Engineering: Design and Material Analyses
Marcia Simbara, Brazil

PS02.009 – Unidirectionally-frozen silk/gelatin scaffolds for cardiac tissue engineering
Siew-Lok Toh, Singapore

PS02.010 – Engineering Mesenchymal Stromal Cells (MSCs) to be More Immunoevasive by Altering Cell Culture Conditions
Sowmya Viswanathan, Canada

PS02.011 – Novel zwitterionic polypeptides for improving resistance to non-specific protein adsorption
Xiaojuan Wang, People’s Republic of China

PS02.012 – Study on preparation and mechanical properties of polyurethane foam with negative Poisson’s ratio
Lizhen Wang, People’s Republic of China

PS02.013 – Proliferation of cardiomyocytes in neonatal, further implication in heart regeneration
Lincai Ye, People’s Republic of China

PS02.014 – Synergetic effects of released ions from CaO-MgO-SiO2-based multiphase bioceramics on osteogenic proliferation and differentiation
Meng Zhang, People’s Republic of China

PS02.015 – Cooling Rate Effects on the Microstructure Evolutions of Biodegradable Mg2Ca Potential Medical Implant Alloy
Li Li Zhou, People’s Republic of China

PS02.016 – Estimation of Compressive and Shear Forces on Lumbar Spine during Lifting by Wii Balance Board
Hieyong Jeong, Japan

PS02.017 – A biomechanical evaluation of a novel pedicle screw-based interspinous device used to stabilize the lumbar spine
Yu-Shu Lai, Chinese Taipei

PS02.018 – Hematological, Biochemical, and End-organ effects of the CH-VAD in Ovine Model
Changyan Lin, People’s Republic of China

PS02.019 – Novel Low-Profile External Fixator with Simple Locking Mechanism Compared with Commercial Available External Device Could Provide Better Stability in Multicycle Dynamic Loadings
Kang-Ping Lin, Chinese Taipei

PS02.020 – A simple external fixation technique for treating bicondylar tibial plateau fracture: a finite element study
Kang-Ping Lin, Chinese Taipei

PS02.021 – Numerical analysis of the elaborate sound amplification mechanism of the mammalian inner ear
Michio Murakoshi, Japan

PS03 – TRACK 03: BIOMECHANICS AND ARTIFICIAL ORGANS

PS03.001 – Musculoskeletal and Finite Element Simulation of Archery
Yahia Al-Smadi, United States

PS03.002 – Dysfunction Screening in Experimental Arteriovenous Grafts for Hemodialysis Using Inflow and Outflow Hemodynamic Game Analysis
Wei-Ling Chen, Chinese Taipei

PS03.003 – The Effects of Limb Dominance, Sex, and Gait Speed on Multisegment Foot Kinematics During Gait
Victoria Chester, Canada

PS03.004 – Investigation of transfibular locking plate to treat open extra-articular distal tibia fractures
Helena Greene, Canada

PS03.005 – Kinematic analysis after total hip arthroplasty during weight-bearing activities
Satoru Ikebe, Japan

PS03.006 – Hematological, Biochemical, and End-organ effects of the CH-VAD in Ovine Model
Changyan Lin, People’s Republic of China

PS03.007 – Estimation of Compressive and Shear Forces on Lumbar Spine during Lifting by Wii Balance Board
Hieyong Jeong, Japan

PS03.008 – A biomechanical evaluation of a novel pedicle screw-based interspinous device used to stabilize the lumbar spine
Yu-Shu Lai, Chinese Taipei

PS03.009 – Hematological, Biochemical, and End-organ effects of the CH-VAD in Ovine Model
Changyan Lin, People’s Republic of China

PS03.010 – A simple external fixation technique for treating bicondylar tibial plateau fracture: a finite element study
Kang-Ping Lin, Chinese Taipei

PS03.011 – Numerical analysis of the elaborate sound amplification mechanism of the mammalian inner ear
Michio Murakoshi, Japan

PS04 – TRACK 04 RADIATION ONCOLOGY

PS04.001 – Image-Guided Intra-arterial Delivery of Yttrium-90 Radioactive Microspheres for the Treatment of Liver Tumors
Muthana Al-Ghazi, United States

PS04.002 – Commissioning of an ASi EPID for patient specific IMRT QA.
David Alonso Fernández, Cuba

PS04.003 – Status of Radiotherapy Treatment in Lebanon
Antar Aly, Qatar

PS04.004 – Verification of VMAT Arc Radiation Therapy Technique for Full Scalp Treatment
Cynthia Araujo, Canada

PS04.005 – Estimating Setup Margins using IGRT Techniques. Preliminary results in Havana
Raul Argota, Cuba
PS04.006 – Uncertainty evaluation of radiation treatment with DIBH for left-sided breast cancer using MV cine imaging
Jae Beom Bae, Republic of Korea

PS04.007 – Evaluation of the Applicability of Pinpoint ion chamber for Dosimetric Quality Assurance of SRS
Jong Geun Baek, Republic of Korea

PS04.008 – Development of a VARIAN 600 C/D Linear Accelerator model using MCNPX 2.6 Monte Carlo code.
Jorge Batista Cancino, Brazil

PS04.009 – A Comparison of Dosimetric Characteristic Between Integrated and Cine Acquisition Modes of a-Si EPID
Omennh Bawazeer, Australia

PS04.010 – Predicting clinical outcomes in locally-advanced non-small cell lung cancer using machine learning focusing on tumor and node imaging features
Nathan Becker, Canada

PS04.011 – Risk estimate of second primary cancers after breast radiotherapy
Eva Bezak, Australia

PS04.012 – A beam angle optimization technique for proton pencil beam scanning treatment planning of lower pelvis targets
Janid Blanco Kiely, United States

PS04.013 – Neutron-Photon mixed field dosimetry by TLD700 glow curve analysis and its implementation in dose monitoring for Boron Neutron Capture Therapy (BNCT) treatments
Esteban Boggio, Argentina

PS04.014 – Boron Neutron Capture Therapy (BNCT) neutron beam at RA-6 reactor: Quality Assurance and Quality Control
Esteban Boggio, Argentina

PS04.015 – Improved Pareto navigation using a plan database with segmented plans
Rasmus Bokrantz, Sweden

PS04.016 – Automated measurement of dwell and tandem position in ring HDR applicators
Bruno Carozza, Canada

PS04.017 – eMU Whisperer: An application for assessing patient surface topology and its impact on monitor units in electron beam therapy
Paule Charland, Canada

PS04.018 – Beam modeling of the flattening filter-free beams for VMAT SBRT using the collapsed cone convolution superposition algorithm
Samju Cho, Republic of Korea

PS04.019 – Dependence of Collimator Angle on Prostate VMAT: A Treatment Planning Study
James Chow, Canada

PS04.020 – Dosimetry of Pacemaker in VMAT for Lung SBRT
James Chow, Canada

PS04.021 – Determination of ion chamber correction factors for small composite fields used by the CyberKnife radiosurgery system
Eric Christiansen, Canada

PS04.022 – One-year review of a real-time, ultrasound-based, single-fraction prostate HDR program ? the Halifax experience
Krista Chytyk-Praznik, Canada

PS04.023 – Retrospective evaluation of visually monitored deep inspiration breath hold for breast cancer patients using edge detection
Leigh Conroy, Canada

PS04.024 – DECT Tissue Characterisation and Artefact Suppression Method for Improved Dose Calculations in Brachytherapy Treatments.
Nicolas Cote, Canada

PS04.025 – Radiotherapy Planning using CEER and CADPLAN in a Prostate Cancer Patient
Juan Alberto Cruz, Brazil

PS04.026 – Impact of increasing irradiation time on the treatment of prostate cancers
Alexandru Dasu, Sweden

PS04.027 – Hemi-body Electron irradiation: Development and Verification of this new technique
Panagiotis Delinikolas, Greece

PS04.028 – Deformable image registration and automatic contouring using Cone-Beam CT imaging: A study of volume statistics and similarity measures
Olivier Fillion, Canada

PS04.029 – Acceptance Modulated Radiation Intensity and Enhanced Dynamic Wedge using 2D Ion Chamber Array
Oscar Garcia Contreras, Colombia

PS04.030 – Dose Calculation in Gynecological Brachytherapy using Monte Carlo simulation for intracavitary treatment of Cervical Cancer
Oscar Garcia Contreras, Colombia

PS04.031 – An inverse treatment planning module for Gamma Knife® Perfexion? using 3D Slicer
Kimia Ghobadi, Canada

PS04.032 – Bladder and rectum DVH prediction: a statistical approach for prostate treatment
Frédéric Girard, Canada

PS04.033 – Retrospective evaluation of applicator localization for HDR cervix brachytherapy ? A comparison of MR versus CT
Lisa Glass, Canada

PS04.034 – A general source model for clinical linac heads in photon mode
Wilfredo González, Spain

PS04.035 – Measurement of the beam quality TPR 20,10 of small radiotherapy fields: Comparison of experimental measurements and Monte Carlo simulations
Eduardo González-Villa, Mexico

PS04.036 – The Effect of Assessment Criteria on Inter-rater Variability in the Evaluation of Skin Reactions following Breast Cancer Radiation Therapy
Riya Goyal, United States

PS04.037 – Two-dimensional probability density function presenting the pre-treatment variability of the rectal wall integrating the variability of the motion of the rectum and the rectal wall thickness
Grigor Grigorov, Canada

PS04.038 – Unbiased Assessment of Detail Detectability in Image Guided Radiation Therapy
Victor Gurvich, United States
PS04.039 – Assessing radiation protection of members living close to patients with implanted 125I seeds in prostate
Takashi Hanada, Japan

PS04.040 – Improvement of MV planar image by elimination of Compton scattered photons and re-projection as primary photons
Masatsugu Hariu, Japan

PS04.041 – Determination of exit fluence by MCNP4 code for IMRT treatment fields and its validation with a conventional EPID system
Benjamin Hernandez Reyes, Mexico

PS04.042 – Accuracy in simulating tumor translation and rotation: Commissioning a motion platform, Hexamotion for tumor motion management QA
Chen-Yu Huang, Australia

PS04.043 – Dosimetric impact of the Acuros XB Algorithm for 25 lung SABR patients treated using the TrueBeam FFF 6MV
Derek Hyde, Canada

PS04.044 – Dynamic resource allocation: Investigating ways to distribute resources in a patient cohort based on plan quality
Elin Hynning, Sweden

PS04.045 – Physical plan evaluation of Head and Neck Cancer at Square Hospital, Bangladesh.
Md. Anwarul Islam, Bangladesh

PS04.046 – IAEA multicentre study of the methodology for advanced dosimetry audit: single IMRT field dose delivery
Joanna Izwieka, Austria

PS04.047 – Electron Density Measurements of Metallic Implants with Cobalt-60 Computed Tomography
Christopher Jechel, Canada

PS04.048 – A Systematic Analysis Of The Error Sources Within The CyberKnife M6 Daily AQA Test
Kevin Jordan, United States

PS04.049 – The Use of Boron Neutron Capture Therapy in the Treatment of Cancer Tumours in the Czech Republic
Ivana Jurickova, Czech Republic

PS04.050 – Partial Arc Breast Boost
Tania Karan, Canada

PS04.051 – Determination of the optimal phase for respiratory gated radiotherapy from statistical analysis using a visible guidance system
Sung Kyu Kim, Republic of Korea

PS04.052 – Dosimetric Verifications of the Output Factors in the Small Field less than 3 cm2 using the Gafchromic EBT2 films and the Various Detectors
Sung Kyu Kim, Republic of Korea

PS04.053 – Methodology to Evaluate Combined EBRT and HDR Brachytherapy for Cervical Cancer using Equivalent Uniform Dose (EUD) and Tumor Control Probability (TCP)
Yusung Kim, United States

PS04.054 – International Multi-Institutional Bench Mark Study on Dosimetric and Volumetric Modulation using Helical TomoTherapy Treatment Planning for Malignant Pleural Mesothelioma Tumors
Tommy Knöös, United States

PS04.055 – Factors predicting of local relapse in irradiated patients with breast cancer: A Syrian Cohort study
Moussa Krayem, Syria

PS04.056 – Automated Routine Quality Assurance of VMAT
Michael Lamey, Canada

PS04.057 – Evaluation of the clinical usefulness of modulated Arc treatment
Young Kyu Lee, Republic of Korea

PS04.058 – A comparison of linac-based IMRT with helical tomotherapy for craniospinal irradiation
Young Lee, Canada

PS04.059 – A Hardware-Accelerated Software Platform for Adaptive Radiation Therapy
Junghoon Lee, United States

PS04.060 – Predicting the Impact of Surgery on Quality of Life and Risk Management in Patients Afflicted with Glioblastoma Multiforme
Luca Li, Canada

PS04.061 – A memetic algorithm for body gamma knife stereotactic radiotherapy treatment planning
Bin Liang, People’s Republic of China

PS04.062 – Gamma evaluation of dose distributions from newly developed dosimetry system for helical tomotherapy
Sangwook Lim, Republic of Korea

PS04.063 – Suitability of a Light Transparent and Electrically Conductive Glass Plate for Construction of a Beam Monitor for Radiation Therapy
Xun Lin, Canada

PS04.064 – Objective assessment of skin erythema caused by radiotherapy
Hiroaki Matsubara, Japan

PS04.065 – Nasopharyngeal carcinoma tumor response to induction chemotherapy followed by concurrent chemoradiotherapy: A volumetric magnetic resonance imaging study
Nevin McVicar, Canada

PS04.066 – Volumetric Modulated Arc Therapy of Pancreatic Cancer: Dosimetric Advantages as Compared to 3D Conformal Radiation Treatment
Xiangyang Mei, Canada

PS04.067 – Application of ExacTrack BrainLab system for Choroidal melanoma treatments using Stereotactic Radiotherapy and a not invasive immobilization system
Artur Menezes, Brazil

PS04.068 – Dosimetric evaluation of deliverable and navigated Pareto optimal plans generated with Multi-Criteria Optimization
Raphaël Moeckli, Switzerland

PS04.069 – 2D and 3D Approximate Entropy Algorithms for On-line Quantification of Threshold Structure Content in Large Radiotherapy Image Data
Christopher Moore, United Kingdom

PS04.070 – Dosimetric effects of seed positioning uncertainties in ophthalmic plaque brachytherapy
Hali Morrison, Canada

PS04.071 – A Method for Evaluating Deformable Dose Accumulation in RayStation
Joanne Moseley, Canada

PS04.072 – Dosimetric comparison between 3D CRT, full Arc and Partial Arc Vmat techniques in the management of locally advanced lung Cancer using External Beam Radiation Therapy (EBRT).
Samir Mouatassim, Marocco

PS04.073 – Dosimetric and clinical considerations for implementing CBCT based adaptive planning using RayStation
Bongile Mzenda, New Zealand
PS04.074 – A Statistical Study based on comparison between two treatment planning systems while exporting RT structure set
Kamlesh Passi, India

PS04.075 – The Characteristics and Implementation of XR-RV3 Gafchromic Film for Radiotherapy Dosimetry
Supriyanto Ardjo Prawiro, Indonesia

PS04.076 – Weighted comprehensive score evaluation of CBCT image guided positioning accuracy in lung cancer radiation treatment
Yinglin Peng, People’s Republic of China

PS04.077 – MCNP Simulation of Leksell Gamma Knife Using Disk Sources for Different Phantom Materials
Ma. Vanessa Francheska Perianes, Philippines

PS04.078 – Dosimetric comparison between RAPIDARC and 3DCRT planning in extremity soft tissue sarcoma
Yannick Poirier, Canada

PS04.079 – Cerebral Functional Alterations Before and After Intensity-Modulated Radiation Therapy in Patients with Nasopharyngeal Carcinoma
Wenting Ren, People’s Republic of China

PS04.080 – A Study of Accuracy from Varian Portal Dosimetry for VMAT Patient Specific QA using Monte Carlo
Mohamad Rhani, Singapore

PS04.081 – A study on improvement method of dose distribution using bolus in boron neutron capture therapy for head and neck tumors
Yoshinori Sakurai, Japan

PS04.082 – Peripheral neutron dose estimation: comparison between experimental measurements and TPS estimation
Beatriz Sanchez Nieto, Chile

PS04.083 – Dual Energy X-ray Stereoscopic Image Guidance for Spine SBRT
Mike Sattarivand, Canada

PS04.084 – Comparison between our EPID-IMRT-QA tool and commercial phantom based QA tools
Otto Sauer, Germany

PS04.085 – Dosimetric assessment of a novel metal artifact reduction tool (iMAR)
Andrea Schwahofer, Germany

PS04.086 – An Image quality and dose comparison between Varian OBI and Elekta XVI CBCT systems.
Amani Shaer, Canada

PS04.087 – An open-source treatment planning system for research in particle therapy: Implementation and dosimetric evaluation
Gregory Sharp, United States

PS04.088 – GMM guided automated Level Set algorithm for PET image segmentation
Chiara Soffientini, Italy

PS04.089 – Impact of the magnitude of MLC radiation leakage in IMRT treatment planning
Jaziel Soto-Muñoz, Mexico

PS04.090 – Modelling multi-leaf collimator defocusing and focal spot partial shielding for TomoTherapy and Elekta accelerators using Monte Carlo methods
Ryan Studinski, Canada

PS04.091 – Can Image-Guided Intensity Modulated Brachytherapy delivery be better than IMRT and classical brachytherapy methods for cervical cancer: A Dosimetric analysis
Vellaiyan Subramani, India

PS04.092 – Analysis on Volumetric and Dosimetric accuracy of Maximum-Intensity Projections based 4DCT for stereotactic body Radiotherapy
Vellaiyan Subramani, India

PS04.093 – 2D/3D registration for compensation of patient positioning error in Korea Heavy Ion Medical Accelerator Center
Tae-Suk Suh, Republic of Korea

PS04.094 – Cardiac movement in deep inspiration breath-hold for left-breast cancer radiotherapy
Tae-Suk Suh, Republic of Korea

PS04.095 – Dosimetric evaluation according to patient set-up errors using biophysical indices in whole breast irradiation
Tae-Suk Suh, Republic of Korea

PS04.096 – Comparison of proton boron fusion therapy with boron neutron capture therapy
Tae-Suk Suh, Republic of Korea

PS04.097 – Verification for prompt gamma ray imaging during proton boron fusion therapy: A Monte Carlo study
Tae-Suk Suh, Republic of Korea

PS04.098 – Feasibility study of flattening filter free beam for stereotactic ablative radiotherapy of localized prostate cancer patients
Tae-Suk Suh, Republic of Korea

PS04.099 – The evaluation of radiobiological and physical impacts based on multi-modality images using in-house software
Tae-Suk Suh, Republic of Korea

PS04.100 – Comparison of Conventional 3D Static Planning and 4D Planning using Dose Warping Technique for Liver SBRT
Tae-Suk Suh, Republic of Korea

PS04.101 – Monte Carlo Design and Simulation of a Grid-type Multi?layer Pixel Collimator for Radiotherapy: Feasibility Study
Tae-Suk Suh, Republic of Korea

PS04.102 – Feasibility study of patient alignment method using tactile array sensors
Tae-Suk Suh, Republic of Korea

PS04.103 – Analysis of motion-induced dose errors according to the tumor motion in helical tomotherapy
Tae-Suk Suh, Republic of Korea

PS04.104 – Drift correction techniques in the tracking of lung tumor motion
Peng Teo, Canada

PS04.105 – Application and Parametric Studies of a Sliding Window Neural Network for Respiratory Motion Predictions of Lung Cancer Patients
Peng Teo, Canada

PS04.106 – VMAT delivery through couch tops: an illustration of loss of dose coverage for prostate plans
Monique Van Prooijen, Canada

PS04.107 – Edge Detection for Automated Biological Tumor Volume Definition Based on FDG-PET/CT-fused Imaging: An Agar Phantom study
Stella Veloz, Colombia

PS04.108 – Comparison between HybridARC and sliding windows IMRT for Spine SBRT tumor
Daniel Venencia, Argentina
PS04.109 – real time dynamic prostate brachytherapy dose calculations using permanent I125 implants: technical description and preliminary experience
Daniel Venencia, Argentina

PS04.110 – Design of a simple device for end to end test of IGRT system using ExacTrac
Daniel Venencia, Argentina

PS04.111 – Study on the use of an in-house device to consider the motion effects on absorbed dose determination and measurements using different calculation algorithms in lung SBRT cases
Victor Villamares-Vargas, Mexico

PS04.112 – In-vivo skin dose evaluation for Pd-103 permanent breast radiotherapy implants
Jose Villarreal-Barajas, Canada

PS04.113 – Dosimetric Variations in Permanent Breast Seed Implant (PBSI) Evaluated at Different Arm Positions using Deformable Image Registration
Elizabeth Watt, Canada

PS04.114 – Minimum Planning Target Volume Coverage Necessary for the Delivery of the Prescribed Dose in Lung Radiotherapy
Marcin Wierzbicki, Canada

PS04.115 – A modified methodology to accurately validate CT number constancy for proton therapy
Richard Wu, United States

PS04.116 – Development of a real-time portable applicator monitoring system for gynecologic intracavitary brachytherapy
Junyi Xia, United States

PS04.117 – Quality Assurance of the Radiotherapy Workflow Integrating a Dedicated Wide-bore 3T MRI Simulator
Aitang Xing, Australia

PS04.118 – Evaluation of deformable accumulated parotid doses using different registration algorithms in adaptive head and neck radiotherapy
Shouping Xu, People’s Republic of China

PS04.119 – Optimization of brain metastases radiotherapy with TomoHDA
Slav Yartsev, Canada

PS04.120 – A Rapid Learning Approach for the Knowledge Modeling of Radiation Therapy Plan
Lulin Yuan, United States

PS04.121 – Plan comparison and delivery verification for intracranial stereotactic treatments using Varian TrueBeam STx linac
Sergei Zavgorodni, Canada

PS04.122 – A method to convert cone-beam computed tomography (CBCT) image for dose calculation and the phantom evaluation
Guangshun Zhang, People’s Republic of China

PS04.123 – Phantom-based evaluations of two binning algorithms for four-dimensional CT reconstruction in lung cancer radiation therapy
Fuli Zhang, People’s Republic of China

PS04.124 – Thermoluminescent dosimetry of the model BT-125-1 125I interstitial brachytherapy seed
Nan Zhao, People’s Republic of China

PS05 – TRACK 05: DOSIMETRY AND RADIATION PROTECTION

PS05.005 – Dose analysis for paediatric patients under cardiac catheterization at Hamad General Hospital in Qatar. A.E.Aly, H.A. Al-Saloos, H.M. Al Naemi Hamad Medical Corporation, Qatar
Antar Aly, Qatar

PS05.006 – In vivo dosimetry implementation with diodes at the National Radiotherapy Center of the Korte-Bu Teaching Hospital, Ghana
Vivian Della Atuwo-Ampoh, Ghana

PS05.007 – Assessment of radiation dose due to radio frequency emitted from medical high voltage modules
Mohammad Reza Ay, Iran

PS05.008 – Software Assisted Skin Dose Calculation in Fluoroscopically Guided Interventional Procedures
Mohamed Badawy, Australia

PS05.009 – Current Statues of a-Si EPID Dosimetry: An Application for Dose Verification in Standard Radiotherapy Techniques
Omenh Bawazeer, Saudi Arabia

PS05.010 – Nanodosimetry of protons in the Bragg peak region based on ionisation cross sections of DNA constituents
Daniel Bennett, Germany

PS05.011 – Micronuclei assessment of Selenium and Vitamin E radioprotective effects in human lymphocytes
Vahid Changizi, Iran

PS05.012 – The Organ ans Skin Dose Distribution in Total Body Irradiation
Samju Cho, Republic of Korea

PS05.013 – Comparison of 6MeV and 9MeV Electron Beams for Total Skin Irradiation
Ricardo Contreras, Guatemala

PS05.014 – Analysis of Informal Commerce Sunglasses using Spectroscopy
Juan Alberto Cruz, Brazil

PS05.015 – Dosimetric Evaluation Of Lung Dose Using Indigenously Developed Respiratory motion phantom
G Dheva Shantha Kumari, India

PS05.016 – Activation of Medical Linear Accelerators
Adam Dodd, Canada

PS05.017 – Assessment of Patient Dose in Selected Non-Cardiac Interventional Fluoroscopy Procedures Using OSL Dosimeters
Isabel Elona, PH

PS05.018 – Measurment of Photon and Neutron Dose Distribution in Cyclotron Bunker During F18 and N13 Production
Pardis Ghafarian, Iran

PS05.019 – Energy response of the GAFCHROMIC EBT3 in diagnosis range
Rumi Gotanda, Japan

PS05.020 – Estimation of In Vivo Dosimetry Accuracy with Dose-Volume Histogram
Victor Gurvich, United States

PS05.021 – Evaluation of the dosimetric properties of water equivalent microDiamond detector in high energy photon beam.
Hyun Do Huh, Republic of Korea

| PS07.005 | Robotic positioning system of ultrasound transducer for ultrasonic therapy  
Shinya Onogi, Japan |
| PS07.006 | Force Modeling of MRI-Compatible Robot for Pediatric Bone Biopsy  
Peyman Shokrollahi, Canada |
| PS07.007 | Comparing the Effects of Three MRI RF Sequences on Ultrasound Motors  
Peyman Shokrollahi, Canada |
| PS07.008 | TRACK 08: BIOSENSOR, NANOTECHNOLOGY, BIOMEMS AND BIOPHOTONICS |
| PS08.002 | Novel Optical Method to Determine Glass Transition Temperature of Polymers  
Yao-Xiong Huang, People’s Republic of China |
| PS08.003 | The Comparison of Temporal Change between Typically Developing Children and Children with ADHD in Rotational Motion Speed of Arms  
MIKI Kaneko, Japan |
| PS08.004 | Photoacoustic Speckle and Spectral analysis of Vasculature Trees  
Muhammad Fadhel, Canada |
| PS08.005 | The algorithm for the diagnosis of ventricular tachycardias from electrocardiogram  
Martin Holub, Czech Republic |
| PS08.006 | Modelling of Platelet and White Blood Cell in Dengue Patients using Bioelectrical Impedance Analysis technique  
Fatimah Ibrahim, Malaysia |
| PS08.007 | Combination of Multiple Signal Processing Techniques for Multi-class Motor Imagery Detection using Mu Rhythm  
Rina Kojima, Japan |
| PS08.008 | The comparison of severity assessment methods of kinetic tremor in Parkinson’s disease using wearable sensors  
Hong Ji Lee, Republic of Korea |
| PS08.009 | Unobstructive blinking detection wearable device utilizing transparent conductive ITO film for smartphone users to prevent of computer vision syndrome  
Jeong Su Lee, Republic of Korea |
| PS08.010 | A Simple, CO2-Based Method to Reconstruct the Molar Mass of the Dried Respiratory Gas within a New Double-Tracer Single Breath Washout  
Johannes Port, Germany |
| PS09.001 | Sensitivity of heart rate variability indices for artificially simulated data  
Anna Alulova, Russian Federation |
| PS09.002 | The Smoothness of a signal as a new feature in Signal Averaged Electrocardiogram that can be used in cardiac electrophysiology diagnosis.  
Mohammad Reza Ay, Iran |
| PS09.003 | Comparison of the Three Filter Algorithms for Detection of Electrically-Evoked Short-Latency Responses in Retinal Ganglion Cells.  
Myoungwhan Choi, Republic of Korea |
| PS09.004 | Photoacoustic Speckle and Spectral analysis of Vasculature Trees  
Muhammad Fadhel, Canada |
| PS09.005 | The algorithm for the diagnosis of ventricular tachycardias from electrocardiogram  
Martin Holub, Czech Republic |
| PS09.006 | Human Knee Simulation Using CMAC ANN  
Lourdes Brasil, Brazil |
| PS09.007 | Development of New Method to Create In-school Tactile Maps for Visually Impaired Children  
Kouki Doi, Japan |
| PS09.008 | Experimental Study on Usability Evaluation of a Hydraulic Jack Lever  
Kouki Doi, Japan |
| PS09.009 | Neuromuscular Reconnection Methodology By Cap Sense Absorption And Diffusion Signal  
Ricardo Jaramillo Diaz, Colombia |

PS12.019 – Device trial to improve blood flow rate with controlled pressure for blood flow at venous side in single needle dialysis
Yasuyuki Miwa, Japan

PS12.020 – An Embedded Software Solution for Rest ECG Devices
Gisela Montes De Oca, Cuba

PS12.021 – Development of innovative gas phase sterilization technology for nucleolytic degradation
Toshihiko Okazaki, Japan

PS12.022 – Ultrasound Modular Platform: a general purpose open architecture system for medical imaging research
Haroldo Onisto, Brazil

PS12.023 – Design and Preliminary Validation of a Dual Mechanical-Anthropomorphic Breast Phantom with Inclusions
Shigeto Ono, United States

PS12.024 – Evaluation and Analysis of the Results of a prototype Medical Device Vigilance System (MEDEVIPAS)
Nicolas Pallikarakis, Greece

PS12.025 – Medical Device Development – Risk Management
Mayur Patel, United Kingdom

PS12.026 – Analysis of the terminology to name medical devices used in Intensive Care Units – ICUs
Pamela Ribeiro, Brazil

PS12.027 – Determination of Breath Acetone in 298 Type 2 Diabetic Patients using a Ringdown Breath Acetone Analyzer
Meixiu Sun, United States

PS12.028 – A study of the differences between uncompresses sound source and compressed sound source gives EEG of human
Takashi Suzuki, Japan

PS12.029 – Evaluation of the interface pressure characteristics over a temperature regulating air-mattress under different surgical positions
Eric Tam, People’s Republic of China

PS12.030 – Continuous cuff-less estimation of systolic blood pressure from pulse wave transit time measured in a chair
Toshiyo Tamura, Japan

PS12.031 – A development of the pressure distribution display which is used in robot hand for the disability
Kenya Tanaka, Japan

PS12.032 – Prototype Development Generating Vacuum for Treating Chronic Wounds Negative Pressure Level Laboratory
Edison Vazquez-Gordillo, Mexico

PS12.033 – Tunable Irradiation System for Corneal Collagen Cross-linking
Liliane Ventura, Brazil

PS12.034 – Electromagnetic high-hydrus gel phantom at a low-frequency band -Improvement in the electrical characteristics by using a carbon microcoil and investigation of its mechanism
Takahiko Yamamoto, Japan

PS12.035 – Examination of Bisphenol A Elution Concentration in Dialyzers
Yoshihisa Yamashita, Japan

PS12.036 – Automation of a Dispersive Raman Spectrometer Using LabVIEW Aiming In Vivo Diagnosis of Skin Cancer
Renato Zangaro, Brazil

PS12.037 – Effectiveness of Ozone-Liquid Mass Transfer aiming Ozone Therapy
Renato Zangaro, Brazil

PS12.038 - Impedance plethysmograph based on reconfigurable hardware for the study of superficial vessels
Laura Castro Acevedo, Cuba

PS12.039 - The study for bioelectric properties of tissue and organ measured by electrical impedance
Toshiaki Nagakura, Japan

PS13 – TRACK 13: INFORMATICS IN HEALTH CARE and PUBLIC HEALTH

PS13.001 – A Method for Parental Engaged Consent in the Perpetual Secondary Usage of Health Big Data
Yvonne Choi, Canada

Murilo Contó, Brazil

PS13.003 – Becoming of Ubiquitous Sensors for Ubiquitous Healthcare
Sergo Dadunashvili, Georgia

PS13.004 – Design and Implementation of an Application for ECG processing in Mobile Phones
René González-Fernández, Cuba

PS13.005 – A Telemedicine System to follow-up the Evolution of Chronic Diseases in the Community
René González-Fernández, Cuba

PS13.006 – Developing an Appropriate and Affordable Expert System for Medical Diagnosis (ESMD) in Developing Countries
Kenneth Nkuma-Udah, Nigeria

PS13.007 – Assessment of Mobile Health Applications
Nicolas Pallikarakis, Greece

PS13.008 – An Investigation into using Pulse Rate Variability to Predict Clinical Events
Usman Raza, Canada

PS13.009 – A simple device producing electrolyzed water for home care
Koichi Umimoto, Japan

PS13.010 – Developing predictive models using retrospective study of liver cancer patients treated with radiation therapy.
Jason Vickress, Canada

PS13.011 – A Study on the Problems for People to have Colorectal Cancer Screening Tests in Japan?-From the Results of Interviews for 30 Adults-
Naoko Fujiwara, Japan

PS14 – TRACK 14: INFORMATION TECHNOLOGIES IN HEALTHCARE DELIVERY AND MANAGEMENT

PS14.001 – DermApp: an application for Android mobile devices for reception and transmission of skin images
Iván Escalona, Venezuela

PS14.002 – Use of mobile devices for prevention in youngsters of risk factors common to chronic noncommunicable diseases
Iván Escalona, Venezuela
PS16.001 – Increasing the health value per dollar spent: How Human Factors can help inform procurement of healthcare technology
Sandra Ahedo, Spain

PS16.002 – Using Heuristic Analysis to support Usability Evaluation of a low risk medical device under development process
Ana Almeida, Brazil

PS16.003 – First Contact with Human Factors and Usability Evaluation in a Junior Research Project by a Biomedical Engineering Student
Ana Almeida, Brazil

PS16.004 – Non-Contact Measurement of Arterial Compliance (NCMAC)
Delran Anandkumar, United Kingdom

PS16.005 – Developing a Quantitative Performance Assurance Risk Classification Model within a Generalized Risk Scoring System
Vishvek Babbar, Canada

PS16.006 – Project Management for Clinical Engineering? Considerations in the evaluation and acquisition of medical equipment for health services in Brazil
Lourdes Brasil, Brazil

PS16.007 – Human Factors for Health Technology Safety: A new book on incorporating Human Factors into the work of biomedical technology professionals
Andrea Cassano-Piche, Canada

PS16.008 – Politics, value and risk: a system to allocate medical equipment funding
Peter Cook, United Kingdom

PS16.009 – Magnetic Resonance system configuration and editing tools
Danilo Da Silva, Brazil

PS16.010 – The Unintentional Irradiation of a Live Human Fetus During a CT Scan: a case study
Jeff Frimeth, Canada

PS16.011 – Device reconditioning service for home-based assistance. How to choose the right approach.
Ernesto Iadanza, Italy

PS16.012 – Approach to the management of infusion systems in hospitals
Ernesto Iadanza, Italy

PS16.013 – A Basic Study on the Measurement of Electromagnetic Fields in a New University Hospital Building Before and After the Hospital Opened
Kai Ishida, Japan

PS16.014 – IAEA database of national dosimetry audit networks for radiotherapy
Joanna Iwieszka, Austria

PS16.015 – Telehealth – Achieving its Promise in 2015
Thomas Judd, United States

PS16.016 – The New Japanese Guidelines for Use of Mobile Phones in Hospitals
Takashi Kano, Japan

PS16.017 – Study on Medical Equipment Location Systems that use RFID Technology
Manabu Kawabe, Japan

PS16.018 – Development of a Regional Prioritization Process for Diagnostic Imaging Equipment Replacements
Petr Kresta, Canada

PS16.019 – Implantable Medical Devices: more Safety with Traceability and Surveillance
Paolo Lago, Italy

PS16.020 – Using standard test methods to ensure quality and maximize supply of personal protective equipment in a time of global emergency response
Ying Ling Lin, Canada

PS16.021 – Creation of a system for the coding of medical devices
Alessio Luschi, Italy

PS16.022 – Establishment of Radiation Qualities for Radiodiagnostics in LCR/ UERJ According to IEC 61267 and TRS 457
Luis Magalhaes, Brazil

PS16.023 – A Healthcare Facilities Qualitative and Multivariate Quantitative Assessment Methodology for Mongolia
Claudio Meirovich, Spain

PS16.024 – Practice of HB-HTA on the Study of HIFU Technology for the Treatment of Prostate Cancer and Uterine Fibroma
Roberto Miniati, Italy

PS16.025 – A Simulation Based Model for Planning Operating Theater Activity in Complex Hospitals: Case Study in Orthopedics
Roberto Miniati, Italy

Sérgio Mühlen, Brazil

PS16.029 – Generate health and wealth by innovation
Mayur Patel, United Kingdom

PS16.030 – Validating and comparing Methods for testing Endothelial Function
Ragu Prakash Ratnakumaran, United Kingdom

PS16.031 – Reliability Indicators in the Medical Equipment Management
Renato Garcia Ojeda, Brazil

PS16.032 – Methodology for Safety Movement of Clinical Facilities Focused in Oncology
Sandra Rocha Nava, Mexico

PS16.033 – Design of a remote use ECG with an Optical Communication System (FSO) for Telemedicine Applications
Raul Rodriguez-Aleman, Mexico

PS16.034 – Adverse events and death related to the use of the MRI equipment
Ricardo Sá, Brazil

PS16.035 – Adverse events and injuries related to the use of the MRI equipment
Ricardo Sá, Brazil
PS16.036 – Investigation on solar aging in sunglasses by developing of automated prototype for sun exposure of lenses
Homero Schiabel, Brazil

PS16.037 – Integral clearance of medical rooms based on the type of medical treatment ensures a safe environment upon first use
Casper Smit, Netherlands

PS16.038 – Real-Time Posture Classification and Correction based on a Neuro-Fuzzy Control System
Pedro Vieira, Portugal

PS16.039 – Management of electromagnetic interferences in healthcare facilities – A Review
Gnahoua Zoabli, Canada

Gnahoua Zoabli, Canada

PS17 – TRACK 17: EDUCATIONAL AND PROFESSIONAL ACTIVITIES

PS17.001 – A discipline about Human Factors Engineering and Usability applied to Medical Devices for under graduation courses using Active Learning techniques
Ana Almeida, Brazil

PS17.002 – The medical equipment management inside the accreditation process: a comparison with the Brazilian accredited hospitals
Rodrigo Almeida, Brazil

PS17.003 – The Medical Physics M.Sc. program at the National University of Mexico: Results and lessons learned after 100+ graduates
María-Ester Brandan, Mexico

PS17.004 – An Experience on the dosimetry of HDR Brachytherapy Treatment Planning of Cervical Carcinoma at BPKM Cancer Hospital, Nepal
Surendra Chand, Nepal

PS17.005 – Health IT Education for Clinical Engineers
Thomas Judd, United States

PS17.006 – Professional Development of Medical Physicists in Radiation Oncology for the Commonwealth of Independent States
Marina Kislyakova, Russian Federation

PS17.007 – Assistive Technologies in Biomedical Engineering Education
Lenka Lhotska, Czech Republic

PS17.008 – Future-Proofing Physics and Engineering in Medicine
Kwan Hoong Ng, Malaysia

PS17.009 – Nuclear and Radiological Emergencies – First IAEA Training Course for Medical Physicists
Fridtjof Nuesslin, Germany

PS17.010 – Academic Real Time Digital Medical Image Processing Environment
Ana Cláudia Patrocinio, Brazil

PS17.011 – Detection of Eye Movement; possibility how to control world
Lucas Peter, Czech Republic

PS17.012 - Artificial Neural Network Interactive Activation and Competition Model Service-Oriented Applied to Health
Lourdes Mattos Brasil, Brazil

PS17.013 – Career Progression for Medical Physicists
William Round, New Zealand

PS17.014 – IOMP-W ? the International Organization for Medical Physics Women Subcommittee
Magdalena Stoeva, Bulgaria

PS17.015 – AAPM/IOMP Used Equipment Donation Program
Mohammed Zaidi, United States

PS19 – TRACK 19: BIOPHYSICS AND MODELLING

PS19.001 – Numerical Modeling Of The Electrical Impedance Method Of Periheral Veins Localization
Mugeb Al-Harosh, Russian Federation

PS19.002 – Modeling current density maps in the heart
Mohammadali Beheshti, Canada

PS19.003 – Finite Element Modeling of Gelatin Phantom from Measured Impedance Spectra
Pedro Bertemis-Filho, Brazil

PS19.004 – Prediction of radiation induced direct and indirect cellular damage using a novel ionisation spatial clustering algorithm
Eva Bezak, Australia

PS19.005 – Research on Vibration of Cell Membrane of Plant Seed with Ultrasonic Excitation
Hui Cao, People’s Republic of China

PS19.006 – The Effect of Applied Force on Arterial Pulse with a New Flexible Pressure Sensor
WENXUAN Dai, Hong Kong

PS19.007 – The Art of Engineering Medicine: A New Fast Non-Invasive Method to Directly Assess Ischemia in Human Diseased Coronary Arteries
Iyad Fayssal, Lebanon

PS19.008 – Influence of the alteration of the flow topology during the abdominal aortic aneurysm growth
Joly Florian, Canada

PS19.009 – Using the DDST to Train and Test Anthropomorphic Robotic Children
Paul Frenger, United States

PS19.010 – The new low-cost metaphase finder for biological dosimetry
Akira Furukawa, Japan

PS19.011 – Concentrated photoactivation: focusing light through scattering
Pedro Vieira, Portugal

PS19.012 – Steered Molecular Dynamic Simulation Approaches for computing the Blood Brain Barrier (BBB) Diffusion Coefficient
Ebrahim Ghafar Zadeh, Canada

PS18 – TRACK 18: GENDER, SCIENCE AND TECHNOLOGY

PS18.001 – Bone density measurements in strontium-rich bone-mimicking phantoms using quantitative ultrasound
Bisma Rizvi, Canada
PS19.013 – The study of the relationship between the scatterer particle size of soft tissue in ultrasonic focal region and the frequency offset of backscattered signal
Jianzhong Guo, People’s Republic of China

PS19.014 – Dynamic Model for Shear Stress-Dependent NO and Purine Nucleotide Production from Endothelial Cells
Patrick Kirby, United States

PS19.015 – Mechanism of Phospholipase as a Potential Anti-Bacterial Drug Revealed by Nonlinear Spectroscopy
Xiaolin Lu, People’s Republic of China

PS19.016 – Cancer stem cells in a hierarchical model of tumour regrowth in five head and neck carcinomas
Loredana Marcu, Australia

PS19.017 – Effects of interaction with electromagnetic field on cell culture of Saccharomyces cerevisiae
Aracely Martínez, Mexico

PS19.018 – Obstructive and Sclerotic Disorders affecting Carotid Blood Flow to the Brain
Onaizah Onaizah, Canada

PS19.019 – Estimation of Tissue Temperature in Tumor Hyperthermia Using Ultrasonic Methods
Xiao-jian Wang, People’s Republic of China

PS19.020 – Modeling of a Photosensitizer Distribution Relevant to Photodynamic Therapy of Malignant Non-Pigmented and Pigmented Tumors
Marta Wasilewska-Radwanska, Poland

SHARPEN YOUR EDGE AGAINST CANCER.

**Edge Radiosurgery: Making radiosurgery an option for more patients.**
Deliver accurate radiosurgery treatments quickly and efficiently with the Edge™ radiosurgery system. Edge's advanced technology enables you to offer powerful, non-invasive radiosurgery treatments anywhere in the body where radiation is indicated. Expand treatment options for patients and gain a competitive edge with the system as dedicated as you are.

*Visit us at IUPESM World Congress 2015. Booth #1234.*

*Learn more about Edge Radiosurgery at varian.com/Edge*

---

Radiation treatments may cause side effects that can vary depending on the part of the body being treated. The most frequent ones are typically temporary and may include, but are not limited to, irritation to the respiratory, digestive, urinary or reproductive systems, fatigue, nausea, skin irritation, and hair loss. In some patients, they can be severe. Radiation treatment is not appropriate for all cancers. See varian.com/use-and-safety for more information.

This paper describes an experimental search for the best wavelets, to reduce Poisson noise in CT.

Five slices containing the posterior fossa from an anthropomorphic phantom and from patients were selected. As their original projections contain noise from the acquisition process, some simulated noise-free lesions were added on the images. After that, the whole images were artificially contaminated with Poisson noise over the sinogram-space. The configurations using wavelets drawn from four wavelet families, using various decomposition levels, and different thresholds, were tested in order to determine de-noising performance. The 10 preselected best filters were Sym4, Bior3.5, Bior3.7, Coif3, Coif5, db3, db45, db8, Sym 20.

The quality of the resulting images was evaluated using Contrast to Noise Ratio (CNR), Human Visual System absolute norm (H1), Mean Structural Similarity Index (MSSIM) and the jackknife free-response methodology. The results were compared with other traditional filters.

The de-noising with wavelet filters improved the image quality of posterior fossa region in terms of an increased CNR (see Fig. 1), without noticeable structural distortions (see Fig. 2).

The wavelet filter Coif 3 (MSSIM = 0.8152) had the best performance. It was also better than Median (MSSIM = 0.7914) or Wiener filters (MSSIM = 0.7796) and similar to Butterworth (MSSIM = 0.8228) to remove similar amount of noise with lower spatial resolution lost.

In Conclusion: Wavelet filtering is an alternative to be considered for Poisson noise reduction in image processing of posterior fossa head CT images.
Euclidean distance was used in the K-NN model. In the leaf node of each decision tree, testing samples are predicted with a K-NN model using the relative spatial location and the structural prior of the liver.

Results

The performance of our method for liver localization was tested on 19 contrast enhanced CT datasets from Visceral challenge (http://www.visceral.eu). We adopted the leave-one-out cross validation using Dice coefficient and Hausdorff distance metric. Compared with AdaBoost and traditional random forest method, our methods had a Dice coefficient of 0.878±0.043 and a Hausdorff distance of 22.13±10.12mm, while AdaBoost with a Dice coefficient of 0.795±0.075 and a Hausdorff distance of 30.94±9.41mm; and traditional random forest with a Dice coefficient of 0.829±0.134 and a Hausdorff distance of 30.42±13.42mm. Paired t-test was used to compare among the three methods, and the difference was statistically significant (p<0.001) except the Dice coefficient of our method and the traditional random forest.

Conclusion

We have proposed a fully automated approach for robust liver localization. As in medical images, anatomy structures are spatially dependent, we applied a spatial KNN model to predict the testing sample from k nearest samples from the same leaf node. Compared with AdaBoost and traditional classification random forest, our method has higher performance.

SP001.3 - Brain Tumor Target Volume Segmentation: Local Region Based Approach

Author(s): Mehdī Astarakī1, Hossein Aslian2
1Biomedical Engineering, IAU Science and Research branch, Tehran/IRAN, 2Medical Physics, International Centre for Theoretical Physics (ICTP) and university of Trieste, Trieste/ITALY

In this paper, we comprehensively evaluated clinical application of local robust-region based algorithms to delineate the brain target volumes in radiation therapy treatment planning. Localized region based algorithms can optimize processing time of manual target tumor delineation and have perfect correlation with manual delineation defined by oncologist due to high deformability. Accordingly, they can receive much attention in radiation therapy treatment planning. Firstly, clinical target volumes (CTVs) of 135 slices in 18 patients were manually defined by two oncologists and the average of these contours considered as references in order to compare with semi-automatic results from different four algorithms. Then, four localized region based algorithms named Localizing Region Based Active Contour (LRBAC), Local Chan-Vese Model (LCV), Local Region Chan-Vese Model (LRCV) and Local Gaussian Distribution Fitting (LGDF) were applied to outline CTVs. Finally, comparisons between semi-automatic results and baselines were done according to three different metric criteria: Dice coefficient, Hausdorff distance, and mean absolute distance. Manual delineation processing times of target tumors were also performed. Our result showed that LCV has advantage over other algorithms in terms of the processing time and afterward LRCV is the second fastest method. LRBAC was the second slowest technique; however, we found that processing speed in LRBAC can be almost doubled by replacing the time-consuming re-initialization process with energy penalizing term. Accordingly, due to high accuracy performance of LRBAC algorithm, it can be concluded that the modified version of LRBAC has the best performance in brain target volumes in radiation therapy treatment planning among other localized algorithms in terms of speed and accuracy.
Costa loss of background information of the image. The proposed method, thresholds, producing flat cutoffs. So, just a small part of the total signal “clipping”, with its amplitude saturated to lower and upper classical model used in almost all ultrasound systems, there is a

However, preserves signal integrity. The proposed log compression is more suitable to human vision, by considering contrast perception and tone differentiation and, since it preserves the echo information, it is better to represent the structures contained in the ultrasonic signal. The proposed method has lead to relative error of less than 0.01% (best case) or 4.5% for the worst case. The proposed method shows potential to reduce compression parameter adjustments for imaging of the anatomical structures of interest.

### SP001.6 - Comparison of Independent Component Analysis (ICA) Algorithm for Heart Rate Measurement Based on Facial Imaging

**Author(s):** Lina Septiana1, Freddy Haryanto2, Kang-Ping Lin3  
1Electrical Engineering, Krida WacanaChristian University, Jakarta/INDONESIA; 2Department Of Physics, Institut Teknologi Bandung, Bandung/INDONESIA; 3Department Of Electrical Engineering, Chung Yuan Christian University, Taoyuan/TAIWAN

This paper deals with the heart rate measurement by performing automatic face tracking and blind source separation of three color channel into independent components. A class of the so-called Independent Component Analysis (ICA) represents a powerful tool for such a detection. Various ICA algorithms have been introduces in the literature; therefore there is a need to compare these methods. In this contribution, two of the most common ICA methods are studied and compared to each other as regarding their ability to recover the independent source signal from normalized RGB of the facial image. These are the Joint Approximate Diagonalization of Eigen matrices (JADE), and the Second Order Blind Identification (SOBI). These two algorithms have been applied to the same data set of RGB traces then compare with commercially calibrated BPV sensor. Both two methods have given approximately consistent results. However SOBI method has shown better accuracy of heart rate measurement over JADE.

**Methodology:** This new log compression method is not only unique for presenting the whole ultrasonic signal compressed to a certain range and not just part of its dynamic range, but for considering more features, such as contrast and its relation to dynamic range and to brightness perceived by the eyes, or visually distinguishing neighboring tones. Our proposed model for logarithmic compression is divided into three stages: compression, mapping and tonal adjustment. The compression presents, on a logarithmic scale, the signal amplitude compressed to the chosen range; the mapping step relates the intensity of the post-compression with a grayscale level using a sigmoid curve that tends to change the contrast in the central intensity levels giving priority to texture perception and improving contrast. The last step takes into account the tonal differentiation (proposed by Liu and Huang), which determines the distance between tones that make them distinct. The proposed method was tested with phantom images obtained with a commercial B-mode scanner that allows the capture of raw data for image and signal post processing. The results were compared to those of traditional compression methods. We have quantified image information loss for each log compression method using the error relative to the original signal information. All image and data processing were carried out using Matlab.

**Results, Discussion and Conclusions:** We noted that for the classical model used in almost all ultrasound systems, there is a signal “clipping”, with its amplitude saturated to lower and upper thresholds, producing flat cutoffs. So, just a small part of the total dynamic range is used in the traditional method, leading to possible loss of background information of the image. The proposed method, whereas, performs better than others in the effectiveness of white imaging adjusted to the human visual system.

**Methodology:** This new log compression method is not only unique for presenting the whole ultrasonic signal compressed to a certain range and not just part of its dynamic range, but for considering more features, such as contrast and its relation to dynamic range and to brightness perceived by the eyes, or visually distinguishing neighboring tones. Our proposed model for logarithmic compression is divided into three stages: compression, mapping and tonal adjustment. SP002 - Stem Cells in Tissue Engineering and Regeneration

SP002.1 - Biomaterials and Regenerative Medicine: Micro-environmental Modulation for Controlled Cell Differentiation and Tissue Development
Author(s): Gilda Barabino1, Stephen Goldman2, Yueh-Hsun Yang3
1 The Grove School Of Engineering, Dean, The City College of New York, New York/NY/UNITED STATES OF AMERICA, 2 Army Institute of Surgical Research, San Antonio/TX/UNITED STATES OF AMERICA, 3 The City College of New York, New York/NY/UNITED STATES OF AMERICA

The engineering and regeneration of tissues and organs holds great promise for the treatment and prevention of disease and is enabled by natural and synthetic biomaterials that serve as anchors for bioactive molecules and cells. Successful creation of engineered tissues requires a thorough understanding of microenvironments that regulate cellular behavior and tissue formation. Microenvironments define the immediate surroundings of a cell and encompass essential mediators such as soluble factors and extracellular matrix molecules bound to the cell and to adjacent cells. Tissue engineering approaches that aim to manipulate culture parameters and emulate natural microenvironments are sought by combining cells, bioactive agents and biocompatible or biodegradable materials in scalable bioreactors. Among these components, scaffolds or hydrogels made of synthetic or naturally derived polymers are fabricated to meet the requirements for cell survival, matrix biosynthesis, mechanical integrity and integration capacity with host tissues and thus provide appropriate three dimensional substrates for cell growth and tissue development. Bioreactor systems do their part by delivering biophysical and mechanical cues to cultured cells in a tunable, well-defined environment, which greatly improve mass transfer efficiency and tissue quality. Lately, adult stem cells derived from different origins such as bone marrow and adipose tissues have become attractive for repair and regeneration of damaged tissues or organs due to their multi-potency and expandable lifespan, yet achieving controlled stem cell differentiation into a desired cell lineage remains challenging. As an important step toward the fabrication of clinically relevant functional tissue replacements, our laboratory has focused on developing combinatorial methods that endeavor to understand the synergy between cells and micro-environmental factors in order to optimize culture conditions for stem cell differentiation and tissue regeneration. This talk will summarize recent examples of tissue engineering strategies for development of cartilage tissue constructs using stem cells, hydrodynamic bioreactors and microfluidic hydrogels.

SP002.2 - Defining the regulatory metrics for regenerative medicine using novel biomaterial tagging strategies
Author(s): Alicia J. El Hai1, Katie Bardsley, Ying Yang2
1 Institute Of Science And Technology In Medicine, Keele University, Stoke-on-trent/UNITED KINGDOM

Biomaterials can provide a useful platform for controlling the regeneration of tissues with or without the use of different types of stem cells. In order to meet the regulatory needs for clinical use, the standards must be established which enable the complex products to be manufactured in a reproducible way. A non-destructive protocol which can define a biomaterial’s degradation and its associated ability to support proliferation and or promote extracellular matrix deposition or differentiation could be an essential tool for process manufacturing in regenerative medicine. To achieve this aim, we have designed fluorescent tagged degradable materials which can be monitored on line non-invasively in vitro for assessment of tissue engineered products and also in vivo for measuring tissue regeneration in vivo. Three fluorescently tagged biomaterials, chitosan, fibrin and poly(ethylene glycol) diacrylate-fibrinogen conjugates, were fabricated and the effect of their degradation on cell proliferation and osteogenic protein production was investigated. Alterations observed in fluorescence retention within the biomaterials and the release of fluorescent soluble by-products accurately quantified degradation and was cross-validated by weight loss measurements. Assessment of biomaterial behaviour with and without cells has been measured in vitro in bioreactors, ex vivo and in vivo in rat models. Degradation was shown to have a significant effect on cellular activities, with faster degradation eliciting a decreased cell proliferation and concurrently an increased osteopontin production. A turnover index (TI), which directly describes the effect of biomaterial degradation on cell behaviour, has been defined, with high TIs for matrix production observed on fast degrading biomaterials. This novel TI has the potential to become an essential tool for tissue engineers as it has the ability to highlight biomaterials which are suitable for various applications, such as cell proliferation or differentiation. This ability to predict cellular reactions and pre-select certain biomaterials before clinical studies would be invaluable tool not only for tissue engineering but for regenerative medicine as a whole and may lead to the development of clinically successful therapies.

SP002.3 - The role of electric fields in promoting precursor cell migration to enhance wound repair
Author(s): Stephanie Iwasa1, Robart Babona-Pilipos2, Milos R. Popovic1, Cindi M. Morshede3
1 Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA, 2 Toronto Rehabilitation Institute, University Health Network, Toronto/ON/CANADA, 3 Department Of Surgery, University of Toronto, Toronto/ON/CANADA

Studies have shown that endogenous electric fields (EFs) are important for directed cell migration and further, externally applied EFs have demonstrated success in promoting wound closure. However, the cellular mechanisms of this therapy remain unclear and limit its potential use. We have previously demonstrated that neural stem and progenitor cells (together termed neural precursor cells, NPCs), undergo rapid and directed cathodal migration in the presence of an EF in vitro. Notably, differentiated NPCs do not undergo rapid and directed migration in the presence of an EF. To build on this finding, fluorescent NPCs are plated on ex vivo spinal cord or brain slices to examine NPC migration in a more biologically relevant environment. Initial results show NPCs migrate in the presence of an EF on spinal cord slices, albeit at a slower speed. We hypothesized that the induced cell migration in the presence of EFs is a generalized feature of precursor cells regardless of their tissue of origin. We tested our hypothesis using skin-derived precursor cells (SKPs), found in the dermal papillae of the skin. SKPs are multipotent and give rise to mesodermal and neural progeny. We examined SKPs colonies isolated in vitro and performed the same migration assay as per the NPCs. Interestingly, unlike in NPC migration where >98% of the cells migrated in the EF, the vast majority of SKP cells did not migrate. Of the few cells that displayed directed migration, ~1% migrated to the cathode while another small subpopulation migrated rapidly towards the anode. We have demonstrated through PCR and live-imaging that NPCs express voltage gated calcium channels (VGCCs) that are critical for migration. Indeed, blocking VGCCs leads to a significant reduction in the speed of migration. We predicted the lack of SKP migration might also be the result of the lack of VGCC expression. However, we found that SKPs expressed similar VGCCs to NPCs, suggesting that this was not the reason for the lack of migration. We next proposed that SKPs were differentiating into mature phenotypes in our culture conditions and hence lost their migratory potential.
ability as was seen with differentiated NPC cultures. Our preliminary staining reveals that a small population of plated cells express the neural precursor cell marker Nestin and we hypothesize that it is this neural precursor subpopulation of SKPs that is demonstrating cathodal migration. We are further characterizing the phenotypes of cells migrating towards the anode. Together these findings suggest that cells maintaining a neural precursor phenotype are responsive to EF’s, regardless of their tissue of origin.

SP002.4 - The role of niche architecture on muscle stem cell division orientation
Author(s): Richard Y. Cheng1, Penney Gilbert2
1Ibme, University of Toronto, Toronto/ON/CANADA, 2Ibme, University of Toronto, Toronto/CANADA

Skeletal muscle is comprised of muscle fibres (myofibres) that are embedded within connective tissue. Reconstruction of the adult muscle tissue relies on a pool of resident committed muscle stem cells (MuSCs) situated between the basal lamina and sarcolemma known as “satellite cells” which express the paired-box transcription factor Pax7 necessary for their specification during embryonic development and long-term maintenance during adult life. To maintain tissue homeostasis, MuSCs undergo asymmetric division to produce a committed daughter cell that repairs damage to local fibers and an uncommitted daughter that repopulates the niche. Upon an injury where extensive regeneration is required, MuSCs undergo symmetric divisions in which two uncommitted daughter cells are produced to expand the myogenic progenitor pool. Recent studies indicate that MuSC ‘stemness’ is contingent on maintaining contact with the basal lamina during division such that asymmetric divisions occur in an apical-basal orientation with respect to the fiber, while symmetric divisions proceed in plane with the fiber (planar). Understanding the molecular mechanisms by which MuSCs undergo cell fate decisions, especially self-renewal, during muscle regeneration is a fundamental goal of modern muscle research.

Using a cyclic compression machine to evaluate the Young’s modulus, we found that the bulk stiffness of regenerating muscle is significantly higher compared to healthy control mice. We propose that these changes manifest due to the increased deposition of extracellular matrix (ECM) components in the MuSC niche immediately after injury. We confirmed this using immunohistochemistry and western blotting and observed that the injured MuSC niche contains increased amounts of aligned ECM components such as collagen, fibronectin, and laminin. In addition, atomic force microscopy on isolated individual fibers revealed significant differences between the stiffness of healthy fibers versus injured fibers, indicating that the increased ECM during regeneration is associated with a stiffer niche, which is an aspect capable of modulating MuSC self-renewal in culture as previously showed. To understand if fibrosis alters the niche architecture by physically restricting apical-basal oriented division, we mimicked the healthy and regenerating niche by culturing isolated muscle fibers within soft (12kPa) and stiff (24kPa) agarose gels. Confocal timelapse microscopy allowed us to track cell division orientations over 48 hours of 3D culturing, and here we report that MuSC in a soft environment had a tendency to divide both in the apical-basal (75%) and planar direction (25%), whereas the stiff environment was permissive for mostly planar divisions (84%). Together, this data suggests that changes in the niche architecture due to increased ECM deposition during regeneration play a significant role in supporting MuSC division orientation.

SP002.5 - Mapping the Stem Cell’s Mechanome using Paired Live Cell Multiplexed Imaging and Modeling
Author(s): Melissa L. Knothe Tate
Graduate School Of Biomedical Engineering, University of New South Wales, UNSW Sydney/AUSTRALIA

INTRODUCTION

A series of studies using model mesenchymal stem cells [1-5], primary embryonic stem cells [6], and primary adult stem cells [7,8], has established the profound role of mechanoadaptation on lineage commitment and tissue genesis. Here we aimed to develop novel methods to allow for live cell multiplexed fluorescent imaging for the spatiotemporal distribution of the cell nucleus, membrane and cytoskeleton concomitant to delivery of controlled mechanical stresses and measurement of sub-cellular strains.

METHODS

Cells were cultured per previous protocols [1,9] to achieve targeted densities and developmental contexts. Cells were tagged at time zero with Con-A conjugated, microbeads [4]. Actin and tubulin were tagged during transcription using BacMem 2.0 assays (Invitrogen) [3]. Live cell membranes and nuclei were stained using Cyto9, Hoechst, and fluorescence-tagged Wheat Germ Agglutinin [3,10]. Thus, the displacement and spatiotemporal distributions of each cellular constituent could be tracked as a function of controlled mechanical environment (Fig 1). Using a paired multiphysics computational model (Comsol) [5], we then mapped deviatoric and dilatational stresses as a function of stem cell mechanoadaptation.

RESULTS

Live stem cell imaging of the nucleus (red), actin (green), tubulin (blue) and compiled cell structure, followed by multicell image, depicting the same cellular constituents spatially. Scale bar: 20 microns.

DISCUSSION

The novel paired imaging and modeling method allows for live cell multiplexed fluorescent imaging of cell/nucleus shape and volume concomitant to monitoring of spatiotemporal actin and tubulin distribution, as well as in situ strain assessment. Akin to mechanical testing of a cell as it evolves and optimizes its structure for prevailing dynamic function, the novel method will enable elucidation of the underlying mechanisms of stem cell mechanoadaptation, potentially paving the way for targeted delivery of physical cues to achieve targeted tissue genesis and healing.

**SP003.1 - The impact of in-homogeneity corrected dose calculations for various clinical HDR brachytherapy sites.**

**Authors:** S V. Jamema, Siji Paul, Reena Devi, Kishore Joshi, Mayur Sawant, Pooja Moundekar, Deepak Deshpande

Medical Physics, Tata Memorial Hospital, Mumbai/INDIA

**Purpose:** To determine and the impact of in-homogeneity corrected dose calculations for various clinical brachytherapy sites, and to quantify the variation between the two algorithms: TG 43 & Acuros.

**Methods:** Various clinical sites have been investigated: surface mould of the nose, base of tongue-tonsil implant, soft tissue sarcoma of the chest wall, breast multi catheter APBI, lip, eyelid implant, and gynaecological applications which consisted of two applicators, namely Vienna and ring made up of polymer and stainless steel material respectively. After the implantation, CT scans were obtained, followed by reconstruction of the implant, dose calculation and treatment delivery. The clinical dose calculations were carried out using TG 43 algorithm, which were then re-calculated using Acuros model based dose calculation (Eclipse v 10, VMS). The dose to the target, OARs were evaluated using the DVH parameters, volumes of various isodose levels (V300%, V200%, V100%, V50%) and isodose distribution.

**Results:** TG 43 overestimated the dose as compared to Acuros for all the implant types. Implants such as eyelid and lip had larger variation >10%, while implants of breast, soft-tissue sarcoma of the chest wall and base of tongue resulted in variation of the order of 5-10%. The gynaecological implants resulted with lowest variation of <5% (Table 1). In surface mould of the nose, the mean dose to the ipsilateral eye resulted in a variation of 11%, while in tongue implant, the dose to the underlying bone resulted in a variation of 9%. In soft tissue sarcoma and breast implant, TG 43 over estimated the dose to the skin by 20 and 35 cGy while the dose to the lung was underestimated by 10cGy per fraction (prescription dose: 4Gy/fraction) (Figure 1). The dose profile at the superficial region was overestimated by 50cGy and 200cGy for lip and eyelid implant.

**Conclusion:** The impact of in-homogeneity corrected dose calculations for various clinical brachytherapy sites, between the two algorithms, TG 43 & Acuros has been quantified.

SP003.2 - A novel QA device for brachytherapy applicator QA
Author(s): Yi Le, Sook Kien Ng, Esteban Velarde, Elwood Armour, John Wong
Radiation Oncology, Johns Hopkins University, Baltimore/UNITED STATES OF AMERICA

Purpose/Objective(s): The commissioning and routine quality assurance (QA) of the source positions for HDR applicators usually requires double exposures of films which is time consuming. The objective of this study is to develop an effective and efficient filmless method for evaluating dwell positions of HDR applicators using a novel QA device.

Materials/Methods: Material. A device that unifies comprehensive real-time mechanical and dosimetric QA measurements has been developed in our institute for routine external beam QA originally and extended to brachytherapy application. This device comprises an imaging surface for receiving multiple energy sources, a camera for measuring and recording data related and a mirror system for directing the energy sources to a stationary camera. The imaging surface has a resolution of 0.25 mm. Source dwell positions QA for HDR ring and tandem (R&T) applicator sets was performed using this device as a case study.

Methods: R&T applicator sets were secured to the imaging surface of the QA device (Figure 1a). Two sets of images of the applicators were acquired by the QA device. First set of images were acquired using fluoroscopy x-ray with dummy marker in the applicators (Figure 1b). This serves as the reference image and provides the markers’ positions for comparison with active source positions. The second set images were acquired using HDR Ir-192 sources (Figure 1c). The images were acquired in integration mode with 20 second integration time. Measurements were repeated five times for each set of applicator and the mean value of the dwell position were determined (Figure 1b). No image registration is necessary since the images were taken by the same device at same location. Data analysis was automated using MATLAB to improve efficiency and eliminate user dependence.

Results: Tandem applicator measurements indicated all dwell positions were within 1.0±0.4mm from the dwell positions to the corresponding dummy markers. The most distal dwell position for the ring applicator was found to be within 1.2±0.7mm from the tip of the dummy mark. Results for symmetric source position analysis are in good agreement with the recommended angle (90°). Using this QA device, the applicator sets only need to be setup once on the imaging surface for repeat measurements.

Conclusions: A method utilizing a novel QA device for HDR applicators QA was demonstrated. The digital high resolution images allow the source dwell positions to be determined quantitatively. Automatic data analysis method significantly reduces time required for repeat measurements.

SP003.3 - Electromagnetic tracking for catheter reconstruction in ultrasound-guided high-dose-rate brachytherapy of the prostate
Author(s): Shyam Bharat1, Cynthia Kung1, Ehsan Dehghan1, Alexandru M. Nicolae2, Ananth Ravi2, Niranjan Venugopal3, Antonio Bonillas1, Doug Stanton1, Jochen Kreucker1

Purpose: The accurate delivery of high-dose-rate (HDR) brachytherapy is dependent on the correct identification of the position and shape of the treatment catheters. In many brachytherapy clinics, transrectal ultrasound (TRUS) imaging is used to identify these catheters. However, manual catheter identification on TRUS can be time consuming, subjective, and operator dependent due to a number of imaging artifacts. We report the use of electromagnetic (EM) tracking technology to determine the position and orientation of catheters inserted in a tissue-equivalent prostate phantom.

METHODS AND MATERIALS: An Aurora EM system (NDI, Waterloo, ON, Canada) was used in this experiment. The accuracy of the EM system was quantified using a three-axis robotic system. In addition, EM tracks acquired from catheters were compared with catheter positions determined from TRUS and CT images, to compare EM system performance to standard clinical imaging modalities. The tracking experiments were performed in a controlled laboratory environment (no EM-signal distorters present), and in a typical brachytherapy operating room (EM-signal distorters present). Additionally, the positional distortion in multiple sensors resulting from the distorting effects of the brachytherapy operating room was characterized.

Results: The robotic validation of the EM system yielded a mean
accuracy of < 0.5 mm for a clinically acceptable field of view in a non-EM-distorting (laboratory) environment. The largest distortion in sensor signal (30 s acquisition at 40 Hz), was associated with the brachytherapy equipment cart placed in the proximity of the EM field generator in the brachytherapy operating room. The achievable system accuracy depended largely on the calibration of the TRUS probe, geometry of the tracked devices relative to the EM field generator, and locations of surrounding clinical equipment. To address the issue of variable accuracy, a robust calibration algorithm was developed and integrated into the workflow. The EM-tracked catheter representations were found to have an accuracy of < 1 mm when compared with TRUS- and CT identified positions, both in the laboratory environment and in the brachytherapy operating room, with the addition of the robust calibration. The proposed mapping technique was also found to improve the workflow efficiency of catheter identification.

Conclusions: The high baseline accuracy of the EM system, the consistent agreement between EM-tracked, TRUS- and CT-identified catheters, and the improved workflow efficiency illustrate the potential value of using EM tracking for catheter mapping in high-dose-rate brachytherapy.

SP003.4 - Dosimetric and radiobiological comparison of volumetric modulated arc therapy, high-dose-rate brachytherapy and low-dose-rate permanent seeds implant for localized prostate cancer

Author(s): Ruijie Yang, Junjie Wang
Radiation Oncology, Peking University Third Hospital, Beijing/CHINA

Purpose: To assess the dosimetric and radiobiological differences among volumetric modulated arc therapy (VMAT), high-dose-rate (HDR) brachytherapy, and low-dose-rate (LDR) permanent seeds implant treatment for localized prostate cancer.

Methods and Materials: Ten patients with localized prostate cancer were selected for this study. Volumetric modulated arc therapy, high-dose-rate brachytherapy and low-dose-rate permanent seeds implant plans were created for each patient. For volumetric modulated arc therapy, planning target volume (PTV) was created by adding a margin of 5 mm to the clinical target volume. Rectum, bladder, urethra and femoral heads were considered as organs at risk. 78 Gy in 39 fractions were prescribed for PTV. The dose prescription was D90 of 34 Gy in 8.5 Gy per fraction for HDR (Ir), and 145 Gy to clinical target volume (CTV) for LDR (I) plans, respectively. The dose and dose volume parameters were evaluated for target, organs at risk and normal tissue. Physical dose were converted to dose based on 2-Gy fractions (equivalent dose in 2 Gy per fraction, EQD2) for comparison of three techniques.

Results: HDR and LDR significantly reduced the dose to rectum and bladder compared with VMAT. The Dmean (EQD2) of rectum decreased 22.36 Gy in HDR and 17.01 Gy in LDR from 30.24 Gy in VMAT, respectively. The Dmean (EQD2) of bladder decreased 6.91 Gy in HDR and 2.53 Gy in LDR from 13.46 Gy in VMAT.

For the femoral heads and normal tissue, the mean doses were also significantly reduced in both HDR and LDR compared with VMAT. For the urethra, the mean dose (EQD2) was 80.26 Gy, 91.23 Gy and 104.91 Gy in VMAT, HDR and LDR, respectively.

Conclusion: For localized prostate cancer, both HDR and LDR brachytherapy were clearly superior in terms of the sparing of rectum, bladder, femoral heads and normal tissue compared with VMAT, with a little higher mean dose to the urethra in LDR. HDR provided the advantage in sparing of urethra compared with LDR.

Conclusions: The high baseline accuracy of the EM system, the consistent agreement between EM-tracked, TRUS- and CT-identified catheters, and the improved workflow efficiency illustrate the potential value of using EM tracking for catheter mapping in high-dose-rate brachytherapy.
SP003.5 - A novel system for real-time planning and guidance of breast HDR brachytherapy

**Author(s):** Eric Poulin¹, Lori Gardi², Kevin Barker², Jacques Montreuil², Jean Pouliot¹, Aaron Fenster³, Luc Beaulieu¹
¹Radio-oncologie, CHU de Quebec, Quebec/QC/CANADA, ²Imaging Research Laboratories, Robarts Research Institute, London/ON/CANADA, ³Radiation Oncology, University of California San Francisco, San Francisco/CA/UNITED STATES OF AMERICA

**Purpose:** In breast interstitial high dose rate (HDR) brachytherapy, the number and positions of the catheters are usually chosen manually using a preimplant CT scan or fixed using 2D ultrasound. Furthermore, there is currently no automated real-time ultrasound guidance system available. In this work, we present a novel system for real-time planning and guidance of breast HDR brachytherapy treatment, using 3DUS.

**Methods:** A computer controlled robotic 3DUS scanner has been designed to fit on a modified Kuske assembly (Elekta Brachytherapy, Veenendaal, The Netherlands). The scanner can be mounted at several positions on the assembly, which allows the user to personalize the position of acquisition, as shown in Fig. 1a. Figure 1b shows the larger field-of-view provided by the hybrid motion of the new 3DUS system. Software modules were developed for the acquisition and reconstruction of ultrasound images. A semi-automatic segmentation algorithm and a needle reconstruction algorithm were integrated into the software to segment the planning target volume and reconstruct the catheters. A tracking module and a catheter optimization algorithm were developed in order to perform real-time planning and guidance of the needle. Linearity, volume and catheter trajectory measurements were performed, using agarose-based phantoms in MRI, CT or 3DUS scanners to validate the new 3DUS system. A new approach, using the template, was used for real-time planning. The method snaps the optimized catheter positions to the available position within the template. The procedure was tested with 14 and 16 catheters, six times each, in an agarose-based phantom with an hypo-echoic mass.

**Results:** The 3DUS acquisition time requires approximately 20s and the catheter optimization algorithm can obtain 10 complete treatments plans, with the corresponding dosimetric indices, in 90s. There were respectively 3.4 % and 1.4 % difference between MRI/3DUS as well as CT/3DUS volume. Both MRI and CT volume were not statistically significantly different from 3DUS volume (Student t-test; p>0.05). The 3DUS system was found to measure efficiently the linear dimensions. The mean angular separation distance between catheter trajectories segmented from 3DUS and CT images was 0.42 ± 0.24 °, while the mean trajectory separation was 0.37 ± 0.17 mm. After the insertion procedure, the real-time approach was shown to enable reduction of the number of catheters without breaking ABS dosimetric recommendations.

**Conclusions:** A novel system was designed and validated for real-time planning and guidance of breast HDR brachytherapy treatment. A modified system could also be used for permanent breast brachytherapy.

**SP003.6 - Investigation of electromagnetic catheter tracking approach for spatial reconstruction of implant geometry in high dose rate brachytherapy of prostate cancer**

**Author(s):** Stephen Macgregor¹, Chandra P. Joshi¹, Andras Lasso², Carey Shenfield¹, Gabor Fichtinger², L. John Schreiner¹
¹Departments Of Physics And Oncology, Queen’s University, Kingston/ON/CANADA, ²School of Computing, Queen’s University, Kingston/ON/CANADA

**Introduction:** An accurate and rapid spatial reconstruction of implanted catheters in planning image space is vital in the high dose rate (HDR) brachytherapy. This work investigates the accuracy of electromagnetic (EM) catheter tracking for CT-based treatment planning of HDR brachytherapy of prostate cancer.

**Methods:** A 16-catheter implant was performed under ultrasound guidance on a tissue-equivalent prostate phantom (Model-053G, CIRS, Norfolk, VA) embedded into a pelvic phantom (Figure 1). Seven PinPoint-128 markers (Beekley, Bristol, CT) on the phantom were used to achieve ground-truth registration between the CT image (2mm slices) and EM tracking space. EM tracking was performed with driveBAY magnetic field generator, and Model-600 (reference) and Model-55 (tracking) EM sensors (Ascension Technology, Shelburne, VT). The EM sensor was inserted sequentially into the catheters to obtain location measurements. Data collection was completed using Plus (www.plustoolkit.org) and SlicerIGT (www.SlicerIGT.org) software, and analyzed in MATLAB. EM tracking was performed at field generator-to-surface distances of 5.5cm and 8.0cm for ultrasound probe inside and withdrawn from the rectum. Catheter tracks were reconstructed from locations measured in EM tracking, and catheter reconstruction error was computed as the shortest distance between the EM tracked points and the catheter centrelines reconstructed with spline curve fitting from the CT image space.

**Results and Conclusions:** Both ground-truth registration and catheter reconstruction were more accurate closer to the field generator, and when the ultrasound probe was withdrawn from the rectum (Table 1). With the probe withdrawn, the sum of RMS errors was less than the catheter diameter and is clinically acceptable. Large range values indicate presence of tracking outliers due to EM tracking inaccuracies in dynamic noise environment (Table 1). These outliers will be eliminated by using extended Kalman filters combining geometric and kinematic constraints; currently a work in progress.

**Acknowledgements:** RideForDad, Prostate Cancer Research Grant (Kingston-Quinte), and Cancer Care Ontario
We report our initial clinical testing of this technique on patients with esophageal cancer treated with high dose rate brachytherapy. Feasibility and workflow based on physician and therapist feedback will be presented. A preliminary assessment of the accuracy of the applicator placement when compared to the current standard of care will also be presented.

### SP003.7 - Endoscopic Tracking for improved Applicator Insertion in Esophagus and Lung HDR Brachytherapy

**Authors:** Robert A. Weersink, Jimmy Qiu, Rebecca Wong, Gail Darling, Jonathon Irish, David A. Jaffray

1Radiation Oncology, University Health Network, Toronto/ON/ CANADA, 2Techna Institute, University Health Network, Toronto/ CANADA, 3Surgical Oncology, University Health Network, Toronto/ CANADA

Intracavitary applicators are used in high dose rate brachytherapy for lung, esophagus and gynecological applications. For lung and esophagus applications, the linear applicators are typically inserted using a combination of endoscopy and fluoroscopy. In the current procedure, endoscopy is used to define the proximal and distal ends of the planned target length. With the endoscope located at these sites, the endoscope and a surface marker are aligned using fluoroscopic imaging. Applicator insertion follows removal of the endoscope, with fluoroscopy guiding placement of the applicator relative to the surface marker. Since visualization is only two-dimensional, applicator placement is prone to error. Furthermore, it exposes staff to unnecessary radiation exposure.

We are developing a new method of applicator insertion that employs tracking and navigation of the endoscope and brachytherapy applicator. The objective is to accurately place the applicator based on direct localization of the endoscopic findings. An electromagnetic tracking device (Aurora, NDI, Waterloo, ON) is fixed inside a standard 8mm diameter flexible endoscope (Olympus). The tracking device measures both position and orientation of the end of the flexible endoscope.

Software developed in-house simultaneously displays and records the coordinates and video stream of the endoscope. If a prior volumetric image has been acquired, the endoscopic recording can be further registered to this image. When the endoscope is at a position of interest, such as the proximal or distal end of the target, the location can be recorded and displayed simultaneously with the position of the endoscope. Multiple points can be recorded. A second tracking device is inserted into the applicator to allow tracking of the coordinates of the applicator. As the applicator is inserted into the esophagus or lung, the previously recorded video is replayed by displaying the closest frame associated with the tracking coordinates of the applicator. The distance of the applicator to the previously recorded points of interest is also displayed as an aid in positioning the applicator. Hence two checks provide confirmation of correct applicator placement: distance to the points of interest and the video frame associated with the location.

**TRACK 04: RADIATION ONCOLOGY**

**SP004.1 - In Vivo EPID Dosimetry Detects Interfraction Errors in 3D-CRT of Rectal Cancer**

**Author(s): Stefano Peca1, Derek Brown2, Wendy L. Smith1**

1Department Of Medical Physics, Tom Baker Cancer Centre, Calgary/AB/CANADA, 2Dept Of Radiation Medicine And Applied Sciences, Moores Cancer Center, UC San Diego, La Jolla/CA/UNITED STATES OF AMERICA

**BACKGROUND**

*In vivo* dosimetry can record the delivered dose during radiotherapy, which may be used to trigger adaptive radiotherapy or other user intervention. We demonstrate the use of our in-house *in vivo* electronic portal imaging dosimetry in quantifying interfraction dose variability in rectal cancer.

**METHODS**

We recorded MV images from nine treatment beams for six patients prone on the belly board, during 4-7 fractions, for a total of 50 measurements. Images were processed with our dosimetry system to produce dose maps. The dose map from the reference fraction was compared to all subsequent ones to determine interfraction delivery variation, yielding 41 dose difference maps.

**RESULTS**

We identified a number of dose discrepancies. In several patients, persistent gas bubbles may result in cumulative dose deviations large enough to warrant adaptive radiotherapy. In one patient, discrepancies in dose resulted from variability of patient positioning with respect to the belly board (see Figure). In two other patients, dose differences were likely due to variations in compression of the abdomen in the board-couch interface. These issues accumulated significant dose differences throughout treatment and were not readily identified by standard imaging procedures.

**CONCLUSION**

We are developing an open-source *in vivo* portal dosimetry method to automatically track delivered dose at every fraction. Results can be used to flag unexpected discrepancies, guide adaptive radiotherapy, modify setup technique, or warrant image guidance. Further data is needed to test applicability with other treatment sites and setups.

**CAPTION TO FIGURE**

Patient F, PA field (GA=0°). (a) Raw EPID images. (b) Lateral view from the TPS showing the imaging plane (red) and the body adapting to the belly board opening. (c) Dose difference maps between the first imaged fraction (Im.Fx.) and five later treatment days. The large horizontal mismatch is located at the edge of the belly board opening (red arrows), indicating inconsistent setup of the patient with respect to the board in the SUP-INF direction. This was verified by visual inspection of the raw images (blue arrows). As well, all dose difference maps are affected by the gas bubble present during the Ref fraction (white arrow).

**SP004.2 - Establishing action thresholds for patient anatomy changes and machine errors during complex treatment using EPID and gamma analysis**

**Author(s): Ophélie Piron1, Nicolas Varfalvy1, Louis Archambault2**

1Département De Radio-oncologie, Hotel-Dieu de Quebec - CHU de Quebec, Quebec/QC/CANADA, 2Département De Physique, De Genie Physique Et D’optique, Universite Laval, Quebec/QC/CANADA

**INTRODUCTION**

Our long-term objective is to use *in vivo* data from daily EPID images to identify patients at risk of deviating from their planned treatment. To achieve this, a gamma analysis is performed relative to a reference fraction. The specific objectives of this work are (1) evaluate the sensitivity for different types of error and (2) evaluate the impact of the treatment modality (step-and-shoot IMRT versus VMAT) on the results.

**METHODS AND MATERIALS**

A homemade head-and-neck phantom was used for all irradiations. A CT scan of the phantom was acquired and clinical treatment plans were applied to it. Errors were introduced and EPID images were acquired. Analysis is performed using the gamma index (3%/3 mm)
relative to a no-error delivery. The fraction of points above certain thresholds and the average gamma value is recorded in every case. Daily reproducibility was also assessed by repeating measurements 5 times.

RESULTS

The errors introduced included: patient positioning, weight losses using a uniform sheet of bolus and leaf errors. Figure 1 and 2 show the fraction of points beyond certain gamma values for patient related errors for both VMAT and IMRT cases. From these figures, it is clear that for similar errors EPID images of arc-based treatments are less perturbed than for step-and-shoot IMRT. Similar results were obtained for errors of different magnitudes. When no error is inserted, 99.4% of pixels have a gamma index below 1 on average using a 1%/1 mm criterion.

CONCLUSION

A wide range of errors was introduced to test the sensitivity of EPID to detect treatment errors. For identical errors, those introduced in IMRT treatments were easier to detect than those introduced in VMAT. This will serve to established personalized action threshold to identify patients at risk of deviating from their planned treatment.
SP004.4 - Radiation field size, junction and MLC QA using amorphous silicon electronic portal imaging device, an efficient approach to improve routine accuracy

**Author(s):** Dany Simard, Karim Zerouali
Département De Radio-oncologie, CHUM - Hôpital Notre-Dame, Montréal/CANADA

**Introduction:** Films have been used for linac QA as a reference 2D detector, but amorphous silicon electronic portal imaging device (EPID) are getting increasingly used for this task even if they offer much lower resolution. EPID is a standard component of modern linacs and it can be used to accelerate QA process. We developed in-house QA tools using EPID to replace films with the objectives of being more efficient, more reproducible, precise, Varian/Elekta compatible and integrated with the QC program database QAtrack+.

**Method:** We designed a phantom to identify beam crosshair on the images with four 5mm diameter truss head screws 4cm apart from the center. The crosshair is marked over 34cm to achieve precise phantom alignment. 10x10cm² and 30x30cm² field limits are also marked with dashed lines to ease jaw projections visualization. Line thickness corresponds to our test tolerances for quick inspection. Our mechanical technician manufactured three high precision copies with a 2D router.

We developed Matlab® EPID image analysis tools to perform fully automatic processing and recording in QAtrack+. We implemented functions that allow accuracy beyond the detector resolution for screw and edge detection. Screws are identified using an image correlation with a screw model followed by a circular Hough transform. An oversampling technique is used to enhance edges detections precision. Distances between screws detected are used to evaluate the magnification factor of the phantom on the detector.

Radiation size QA phantom allows light field check (30x30cm²), light/radiation field coincidence (10x10cm²) and radiation field verification (other field sizes).

Junction QA does not require the phantom. Images are integrated over 20MU to remove any effects of beam stabilization on this oversensitive test (Typical edge gradient of 3% / 0.1mm). Four quarter fields are delivered on the portal imager, by moving the jaws, and then summed to get one junction image. Profiles across the four junctions are analyzed to determine the percentage of local dose variation.

MLC positioning QA consists of portal images acquired for different field sizes collimated with the leaves. To get all MLCs over a 40 cm field at isocenter, two half-blocked images are acquired with opposite EPID lateral translation.

**Results:** For all phantoms, distances of 80.08±0.07mm between screws have been measured with a digital caliper. Magnification factor accuracy of 0.2% has been attested by comparing EPID and film profiles acquired simultaneously. Radiation size QA with EPID was compared with film QA and an average absolute difference of 0.3mm have been observed on jaws opening. Using EPID, we are able to reproduce measurements within a standard deviation of only 0.2mm, 3 times lower than film. Similar reproducibility gain is observed for monthly clinical measurement. An average absolute difference of 0.3mm has also been observed between MLC positioning QA with EPID and film QA.

**Conclusion:** We demonstrated that our in-house QA using EPID achieves our objectives: efficiency, reproducibility, precision, compatibility and integration. We replaced films for regular QA and we are working to develop new tests using EPID technology to enhance our QA program.

SP004.6 - Real-time detection of deviations in radiotherapy beam delivery using a head-mounted detector

**Author(s):** Richard Canters1, Martijn Kusters2, Juergen Oellig2, Juan-Pablo Carrasco2, Henk Huizenga2
1Radiotherapy, Radboud UMC, Nijmegen/NETHERLANDS, 2IRT Systems GmbH, Koblenz/GERMANY

**Purpose:** Correct delivery of the planned treatment is of vital importance in radiation therapy. To be able to monitor beam delivery online, the Integral Quality Monitor (IQM, IRT Systems GmbH) was developed. Mounted on the linac head it enables real-time, per-segment evaluation of the delivered beam. In this study we tested the sensitivity for potential errors in a variety of beams on an Elekta linac with MLCi2 head as a beta test in the last development stage.

**Methods:** We incorporated various forced deviations/errors in four treatment plans (stereotactic lung, lung (VMAT), larynx (VMAT), and head & neck (IMRT)):

An unintentionally performed re-optimization of the beams after plan approval by the radiation oncologist

Incorrect number of monitor units (MU) in two segments of 10, 5, or 2 MU. The beam MU remained the same.

Incorrect leave positioning (retraction of leaves by 1, 0.5, or 0.2 cm) in a single segment.

The clinical beams, without incorporated errors, are used as a reference.

For VMAT beams, we have chosen to smooth the IQM signal over the segments with a Gaussian filter to account for the exact segment timing. Evaluation takes place on the maximum difference in a segment and in the cumulative signal, with respect to the clinical beam. Additionally, the clinical beams were measured repeatedly to take into account machine variations.

As a comparison, all beams are additionally measured with the Delta4-system (Scandidos), the standard QA tool in our department. Analogously to the IQM measurements, the clinical beams are used as references. Median dose difference (DD50) and 95% dose difference (DD95) are assessed as measures of agreement between the beams.

A receiver-operating characteristic (ROC) curve is created by varying the cut-off criterion for error detection to assess the sensitivity and specificity of error detection.

**Results:** In figure 1, the results of the IQM and Delta4-system measurements are plotted. The left graph shows the IQM results, where modified beams can be clearly distinguished from reference beams. In the Delta4-measurements (middle graph) this effect is less pronounced. This is confirmed by the ROC-curve (right graph), which shows an improved sensitivity and specificity for error detection by the IQM system compared to the Delta4 system.

**Conclusions:** Our tests of the IQM system on the MLCi2 linac show an excellent sensitivity and specificity in error detection during beam delivery, even for very small deviations in a single segment.
**SP005 - Patient Specific QA**

**SP005.1 - Verifying dynamic planning in gamma knife radiosurgery using gel dosimetry**

**Authors:** Gopishankar Natanasabapathi1, Subbiah Vivekanandhan2, Ss Kale1, G K. Rath3, R K. Bisht1, P Agarwal3, P Sathiaraj4, B S. Sharma1

1Gamma Knife Unit, All India Institute of Medical Sciences, New Delhi/INDIA, 2Neurosciences Centre, All India Institute of Medical Sciences, New Delhi/INDIA, 3Radiation Oncology, All India Institute of Medical Sciences, NEW DELHI/INDIA, 4VIT, VELLORE/INDIA

**Purpose:** To assess dynamic planning based on convolution based algorithm (CABP) in Gamma Knife using gel dosimetry. Materials and Methods: PAGAT gel was prepared and filled into cylindrical container of size 8 cm in diameter for verification. An old MRI distortion phantom was modified to accommodate the gel cylinder. Advantage of this modification is that it avoids the use of metal post and pins in the vicinity of the dosimeter which causes artifacts while scanning. A X-ray CT scan was done on the phantom with cylinder positioned in the middle region. CT scanning parameters were: Tube Voltage – 120 KVP, Tube Current – 57 mAs, Slice thickness – 1.0 mm, FOV – 265 x 265 mm2. A treatment plan was generated in Leksell Gamma Plan TPS (LGP version 10.1) using CT images of the gel phantom. Using HU values and Electron density information CABP was activated. A single shot plan with third level dynamic planning option was generated using CABPMRI with following parameters were used for scanning: CPMG sequence with 8 TE values, FOV – 256, Matrix size – 256, TR – 5000 ms, slice thickness – 1.2 mm. Results: Gamma analysis of the verification showed a pass rate of more than 83 %. This is the first kind of study for three dimensional verification of dynamic planning using convolution algorithm in Gamma Knife Perfexion. Conclusion: We propose gel dosimetry as an essential dosimeter for verifying convolution algorithm in Gamma Knife. Further experiments required to validate the verification with close agreement.

**SP005.2 - Influence of Jaw Tracking in Intensity Modulated and Volumetric Modulated Arc Radiotherapy for Head and Neck Cancers – A Dosimetric Study**

**Authors:** Karthick Raj Mani1, Kh Anamul Haque2, Mohammad Anisuzzaman Bhuiyan1, Kolipillai Joseph Mariadas3

1Radiation Oncology, United Hospital, Dhaka/BANGLADESH, 2Radiation Oncology Unit, United Hospital, Dhaka/BANGLADESH, 3Department Of Radiotherapy, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow/INDIA

**Aim:**

To Study the dosimetric advantage of the Jaw tracking technique in Intensity Modulated Radiotherapy (IMRT) and Volumetric Modulated Arc Therapy (VMAT) for Head and Neck Cancers.

**Materials & Methods:**

We retrospectively selected ten previously treated Head and Neck cancer patients stage (T1/T2, N1, M0) in this study. All the patients were planned for IMRT and VMAT with Simultaneous Integrated Boost (SIB) technique to deliver a differential dose per fraction to the high, intermediate and low risk volume using a single plan. We intend to deliver 70 Gy to the high risk volume, 64 Gy to the intermediate risk volume and 56 Gy to the low risk volumes in 35 fractions. All
the critical structures were delineated which includes both parotids, spinal cord and both sub mandibular glands. Eclipse treatment planning system, version 11.0 (Varian Medical Systems, Palo Alto, CA), was used in this study. All the plans were planned with 6MV photons using Millennium 120 MLC. Both IMRT and VMAT plans were planned with and without jaw tracking by keeping the same constraints and priorities for the target volumes and critical structures for a particular patient. Plans were normalized at the target mean of the high risk volumes. All the plans were accepted with the criteria of parotid glands mean dose <25Gy and spinal cord maximum point dose <45Gy without compromising the target volumes. Target conformity, dose to the critical structures and low dose volumes were recorded and analyzed for IMRT and VMAT plans with and without jaw tracking for all the patients.

Results & Discussion:

Jaw tracking resulted in decreased dose to critical structures in IMRT and VMAT plans. But significant dose reductions were observed for critical structure in the IMRT Technique with jaw tracking compared to IMRT technique without jaw tracking. In VMAT with jaw tracking technique the dose reduction to the critical structure were not significant compared to the without jaw tracking technique due to relatively lesser monitor units. Gamma analysis showed greater than 97% of pixels were passed within 3mm distance and 3% dose criteria for all the plans.

SP005.3 - Evaluation of the eye lens dose according to patient setup errors in pediatric head CT examination

**Author(s):** Rumi Gotanda1, Toshizo Katsuda2, Tatsuhiro Gotanda3, Kazuki Noguchi4, Erika Nakajima5, Takuya Akagawa6, Nobuyoshi Tanki4, Tadao Kuwano7, Tetsunori Shimono7, Yasuyuki Kawaji7, Hitoshi Sato1, Yoshihiro Takeda2

1Department Of Radiological Sciences, Ibaraki Prefectural University of Health Sciences, Ibaraki/JAPAN, 2Department Of Human Relation, Tokai Gakuin University, Gifu/JAPAN, 3Department Of Radiological Science, Faculty Of Health Sciences, Junshin Gakuen University, Fukuoka/JAPAN, 4Department Of Radiological Sciences, Ibaraki Prefectural University of Health Sciences, Ibaraki/JAPAN, 5Graduate School Of Health Sciences, Okayama University, Okayama/JAPAN, 6Osaka Center For Cancer and Cardiovascular Diseases Prevention, Osaka/JAPAN

According to the 2011 ICRP statement, the threshold in absorbed dose for the lens of the eye is now considered to be 0.5 Gy. Therefore, it is important to keep the eye lens doses during head computed tomography examination as low as reasonably achievable. In preliminary study, the surface doses became smaller with decreasing distance from the X-ray tube. Therefore, decreasing the distance from the lens to the X-ray tube (i.e. raising the bed position) is a simple and effective way to reduce the absorbed dose of the lens. However, the occiput doses became higher with increasing distance from the X-ray tube. In this study, the two lenses and the occiput doses associated with patient setup errors and head size were evaluated using phantoms developed for pediatric patients. The phantoms were made using flexible acrylic sheets in a cylindrical shape [diameters of 6 (premature baby), 8 (neonate), 10 (infant), and 12 cm (child)] and placed on the end of the CT bed. The bed position was raised from the center for each phantom size. The two lenses and the occiput doses at each setup were measured using radiochromic film. By raising the bed position, the lens doses decreased at all phantom sizes. However, the occiput doses increased at a complex manner according to the phantom size. The absorbed dose ratio of the two lenses and the occiput at φ8 cm phantom are shown in Fig. 1. In this study, raising the bed position is an effective way to reduce the absorbed dose of the lens. However, when the occiput was positioned at the center of the gantry aperture, the occiput dose peaked in all phantom sizes. In addition, the results indicated a complex dose distribution in pediatric head CT when taking into account the bed position (patient setup errors) and phantom sizes. Furthermore, beam slice width and pitch are significant factor in determining the maximum absorbed dose. To keep radiation doses during CT examination as low as reasonably achievable, it is important to clarify the influence of CT scanning settings on CT dose.

![Fig. 1. Absorbed dose ratio at φ8 cm phantom.](image)

**SP005.4 - Multi-Point Sources on Skin to Assess the Annual Effective Dose by Usage of TENORM added Pillow**

**Author(s):** Do Hyun Yeo1, Wook-Geun Shin1, Jae Kook Lee2, Yeon Soo Yeom3, Chan Hyeong Kim3, Chul Hee Min1

1Department Of Radiation Convergence Engineering, Yonsei University, Wonju/KOREA, 2Korea Institute of Nuclear Safety, Daejeon/KOREA, 3Department Of Nuclear Engineering, Hanyang University, Seoul/KOREA

Consumer products containing Technically Enhanced Naturally Occurring Radioactive Material (TENORM) have been distributed in our life. After the accident of Fukushima nuclear power plant, the law called as ‘Act on Safety Control of Radioactive Rays around Living Environment’ has been implemented to prevent the unnecessary radiation exposure to the public in KOREA. However, the appropriate method to effectively evaluate the exposed dose with TENORM added consumer product was not developed despite the law was into effect from July 2012. The aim of this study is to evaluate the exposed dose with the usage of TENORM added consumer product with Monte Carlo simulation. To assess the annual effective dose, the Monte Carlo method and computational human phantom was employed and the point source on the skin was suggested to effectively determine the various product shape and location.

For the assessment of effective dose with the radionuclide in a consumer product, Polygon-Surface Reference Korean-Man (PSRK-Man) phantom composed of high resolution polygons to represent the organs was developed. To represent the source location of the radioactive material in the product, polygons on skin under the product was selected and the source was generated in the weight center in each polygon. To validate the method defining the point sources on skin later than the realistic source distribution in the product shape and location, organ dose was compared with 1 MeV gammas isotropically emitted in the assumption of the pillow usage with Monte Carlo method using Geant4 tool kits.
Our simulation study shows that the multi-point sources defined on the skin indicate the conservative dose assessment than the sources in the product being modeled because of the close source definition to organs. For bone, skin, and muscle, the organ dose using modeling source was, however, higher than the point source with the increased effective angles. This indicates that increasing the source to organs distributed through the whole body distance could decrease the self-attenuation by other organs. The effective dose with the point source and modeled source was assessed as 5.56E-17 Sv/particle and 2.97E-17 Sv/particle, respectively.

The current study shows the potential method for the evaluation of effective dose by the TENORM added products by using the Monte Carlo method. The comparison study also showed that the various shape and usage location of products could be replaced with the point source on the skin. The data based for the exposed dose by whole the point source could enable the effective and convenient assessment of annual effective dose. This technique could also be used for the other field for radiation protection to calculate the effective dose.

SP005.5 - Patient-Specific Quality Assurance of Respiratory-Gated VMAT Using a Programmable Cylindrical Respiratory Motion Insert for the ArcCHECK™ Phantom

**Author(s):** Heather Young1, Kevin J. Jordan2, Stewart Gaede2
1Engineering, University of Waterloo, Waterloo/CANADA, 2Department Of Medical Biophysics, Western University, London/ON/CANADA

**Introduction:** The ArcCHECK™ phantom is a commonly used four-dimensional detector array for dose delivery verification of IMRT and VMAT. Although the isotropy of this device bodes well for ensuring accuracy for entrance dosimetry per control point, the composite 3D dose distribution may not be accurately represented for tumour sites influenced by respiratory motion. Motion management strategies, such as gating, often requires additional procedures and equipment to ensure accurate delivery. Here, we present a customized programmable moving insert for the ArcCHECK™ phantom that, in a single delivery, can verify both entrance dosimetry, while simultaneously verifying the delivery of respiratory-gated VMAT.

**Methods:** The QUASAR™ Cylindrical Respiratory Motion Phantom consists of a computer-controlled stepper motor used to move interchangeable cylindrical inserts inside a stationary sleeve placed within the bore of the ArcCHECK™ phantom (Figure 1). To demonstrate its effectiveness for patient specific QA, 4D-CT scans of 8 early-stage lung cancer patients previously treated with gated SBRT were used to characterize the tumour motion and was inputted into the programmable software used to drive an A1SL ion chamber insert. CT images of the ArcCHECK™ with the programmable insert were acquired at multiple static positions in 1mm increments.

Respiratory-gated VMAT plans were recalculated on the phantom scan corresponding to the amplitude of the tumour motion measured with 4D-CT. Each plan was delivered under static, moving (while non-gated), and moving (while gated) conditions. For each patient, standard ArcCHECK™ measurements were compared to the planned dose distributions using SNC Patient 6 software using standard gamma analysis with 5% threshold, 3% dose-difference, and 3mm distance-to-agreement and the measured dose to the A1SL chamber, located at isocentre, was compared to the planned dose.

**Results:** The pass rate for the static delivery ranged from 98.1% to 99.6%, suggesting a valid phantom setup for entrance dosimetry. The pass rate was not altered for any measurement delivered under motion conditions. A similar result was observed under gated VMAT conditions containing multiple beam holds and dose-rate ramp-up and ramp-down. For six patients, the measured dose to the A1SL ion chamber was within 3% of the planned dose. The maximum dose difference was 5.1% in one patient where the chamber was located in a large dose gradient.

**Conclusions:** Patient-specific respiratory-gated VMAT verification can be efficiently performed in a single delivery with the ArcCHECK™ phantom containing a moving cylindrical insert.

SP006 - Dosimetry in CT

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP006.1 - Dosimetry and Radiation Protection
Author(s): Virginia Tsapakis
Konstantopouilo General Hospital, Athens/GREECE

It is an actual fact that the primary and most common application of radiation until today is in medicine. Furthermore, medical technology has taken a remarkable boost the last few decades both in patient therapy and medical diagnosis. Not only do we have a big variety of medical equipment but we can access all patient data so much easier than 10 or 20 years ago that is really spectacular. Evolution led us so quickly from soft copy to CD-ROM and now icloud that we sometimes ask ourselves how it was possible to work as we did 5 or 10 years ago. All this has resulted not only on a manifest increase in the number of procedures, but also an expansion into different areas of medicine and the creation of new medical specialties. Presently, complex radiation-based tools and techniques are used in most areas of modern medicine and by specialists who have differing levels of knowledge about radiation, dose and the risks posed to human health by ionising radiation.

Within this context, it is very important to use medical radiation technology with prodigious care due to the presence of ionizing radiation. To put the issue in perspective, the current annual collective dose estimate from medical exposure in the United States has been calculated as roughly equivalent to the total worldwide collective dose generated by the nuclear catastrophe at Chernobyl. Therefore accurate measurement of radiation dose is of utmost importance, not only for patients but also for members of the staff, specially due to the recent International Commission on Radiological Protection reduction in the dose limit for the eye lens of workers (from 150 mSv per year to 20 mSv in a year).

Dosimetry seems to play a fundamental role in the process of developing various radiation protection programs to fit the needs of radiation workers and members of the public, particularly as they relate to mitigating potential health risks from exposure to radiation. Specially due to the fact that there is broad discussion the last years on the possibility that radiation dose received by patients from modern diagnostic examinations can be at a level of significance for the induction of cancer across a population. Moreover, in a number of cases, in the acute damage to particular body organs such as skin and eyes.

The talk will cover the trends in dosimetry and radiation protection focused in diagnostic radiology, image-guided intervention procedures and nuclear medicine studies, illustrated by progress in science and practice of risk communication and changes in societal expectations, and examines challenges that will confront radiation risk communication in the future.

SP006.2 - Organ dose reduction while using in-house CBCT patient-specific protocols based on OSL dosimetry.
Author(s): Etienne Létourneau1, Fabiola Vallejo1, Nancy El Bared2, Danny Duplan1, Martin Hinsé1
1Radio-oncologie, Centre intégré de cancérologie de Laval, Laval/ CANADA, 2Université de Montréal, Montréal/CANADA

Purpose/Objectives
In radiation therapy, dose contributions coming from planning and patient positioning images can seem negligible compared to the treatment dose. However, radiation-induced complications are numerous even at low dose. In order to diminish undesirable effects to the patient, one must concretely apply the ALARA principle and minimize dose to organs at risk (OAR) while not compromising treatment quality. In this study, appropriate adjustments to cone beam computed tomography (CBCT) imaging protocol parameters were performed. This was achieved after measuring the dose to organs in an anthropomorphic phantom filled with optically stimulated luminescent detectors (OSL). All these modifications lead to a significant dose reduction of at least 50% up to a reduction of 90% in comparison with the default protocol doses while still preserving a proper image quality for positioning.

Materials/Methods
Output measurements of the CBCT X-ray tube were performed at 100 kVp and 120 kVp. Measurements were based on the AAPM Task Group 61 protocol using a Farmer-type ionization chamber calibrated for the corresponding beam quality. Once the outputs were determined at the reference point, the correlation between OSL’s number of counts and the resultant dose was achieved. An anthropomorphic adult phantom with heterogeneous densities and 271 plugs for OSL detectors covering the whole body was used. Default scan protocols of the head and neck, breast, chest and pelvis were investigated. The mean dose and the maximum dose to the organs were collected over multiple scans to assure the reproducibility of the given method.

Results
The maximum dose to any given organ never exceeded 3.0 cGy for all the default protocols. For the particular head and neck cases, the maximum dose never reached more than 0.4 cGy. Radio-sensitive organs such as lungs, breasts, bone marrow, stomach and intestines received between 1.0 cGy and 2.0 cGy per scan. In the chest and pelvis protocols, the thyroid gland and the testis received more dose than the other organs (2.0 - 3.0 cGy) due to their proximity to the surface and the low attenuation of the beam before reaching the OSLs.

Conclusions
With the new modifications made to the default scan parameters, a considerable organ dose reduction of at least 50% can be achieved for every protocol without compromising image quality for patient positioning. With our in-house protocols, no organ received more than 1.5cGy per scan. These results are therefore in compliance with the ALARA principle. Also, a new ultra-low dose scanning protocol for the chest was introduced giving only 0.1 cGy to the lungs and 0.2 cGy to the heart and thyroid respectively. This significant dose reduction is desirable especially for young lymphoma patients.

SP006.3 - A novel tool for in vivo dosimetry in diagnostic and interventional radiology using plastic scintillation detectors
Author(s): Jonathan Bolvin1, Sam Beddar2, Maxime Guillemette3, Luc Beauleau4
1Département De Radio-oncologie Et Axe Oncologie Du Centre De Recherche Du Chu De Québec, CHU de Quebec, Québec/CANADA, 2University of Texas MD Anderson Cancer Center, Houston/TX/UNITED STATES OF AMERICA, 3Genie Biomedical, Institut universitaire de cardiologie et de pneumologie de Québec, Québec/CANADA, 4Département De Physique, Génie Physique Et D’optique, Et Centre De Recherche Sur Le Cancer, Université Laval, Québec/CANADA

Plastic scintillation dosimetry is now spreading in multiple areas of clinical practice either for quality assurance or in vivo dose monitor-
The study of the radiation dose distribution over the phantom’s eyeball was carried out using a Philips Allura Xper FD20/20 system (80 kV, 3 fps acquisition mode). Gafchromic XR-RV3 film was used to measure absorbed dose at positions corresponding to the surface of the cornea, under the cornea, under the lens, and on the retina of the eye.

**Materials and Methods:** CT images of head of 13 patients were successfully fabricated and used to evaluate eye lens dose during diagnostic fluoroscopy procedures.

**Purpose:** To fabricate an anthropomorphic phantom for patient’s radiation dose measurement during diagnostic X-ray procedures.

**Conclusion:** A custom made anthropomorphic head phantom was successfully fabricated and used to evaluate eye lens dose during diagnostic fluoroscopy procedures.

**Introduction:** Absorbed dose in CT exams can be ten times higher than in other common procedures of X-ray imaging and must
be monitored. Dosimetry in CT is still commonly made obtaining CTDI100 values, measured with a “pencil” chamber inside a CT phantom, in a single beam slice and no table movement. In helicoidal and multi-slice tomography with high number of rows, measured values of CTDI100 should underestimate accumulated dose at point z=0, as they don’t include the contribution of dose profile «tail», caused by scattering in the phantom (or tissue). In this sense, this work aimed to contribute to review the assessment of Dose in CT according to the methodology suggested by AAPM TG 111 [AAPM, Report 111, 2010].

**Methodology:** Firstly, we have used a Radcal 0.6 cc chamber, previously calibrated in CT standard beam qualities [IAEA, TRS 457, 2007] against a Farmer chamber, to measure dose profiles on a Toshiba Aquilion One scanner (HIAE), through several adjacent slices. Values of Equilibrium Dose free in air, Deq,ar, were obtained for various protocols and pitch values. In the second step, using a large CT phantom (Fig.1), values of central Cumulative Dose (DL(0)) were measured for different slice length values (L), for two different abdomen protocols, in order to evaluate the Equilibrium scanning length (Leq) and Equilibrium doses (Deq) (Fig.2). Finally, Planar Average Equilibrium Dose (Deq,p) was evaluated and compared with CTDIvol values displayed in the CT equipment.

**Results and Discussion:** In the survey of dose profiles, slice thickness was evaluated with 19-28% difference compared to the nominal value. It was also observed that Equilibrium Dose free in air increases as the pitch is reduced and that the values of equilibrium dose-pitch product free-in-air (p.DEQ, air) are constant. As expected, differences between Planar Average Equilibrium Dose and CTDIvol ranged between 30-37%.

**SP007 - Biomedical Signal Quality Analysis**

**Track 09: Biosignal Processing**

**SP007.1 - Biosignal Processing**

**Author(s):** Adrian D.C. Chan

**Systems And Computer Engineering, Ottawa-carleton Institute For Biomedical Engineering, Carleton University, Ottawa/ON/CANADA**

At the end of this presentation you will be able to:

1) explain the need for biomedical signal quality analysis
2) discuss the challenges in biomedical signal quality analysis
3) describe some of the advances in biomedical signal quality analysis

The democratization of technology is being fueled by technology that is decreasing in size, cost, and power-consumption, while the levels of computing power and interconnectivity are increasing. In healthcare, so called patient-empowering, information-leveraging (PI) technologies are drastically changing the paradigm of biomedical monitoring. Traditionally, biomedical monitoring is performed intermittently by a trained expert, under well-controlled conditions, whereas advances has made it easy for frequent or continuous monitoring; in addition, neither the monitoring environment nor the subject’s activity is controlled necessarily (e.g., monitoring can be performed in the home while performing normal activities of daily living). These technologies are not only non-invasive but also non-obtrusive; they can be wearable devices, or integrated into other devices or environments where they may remain unnoticed by the subject. Multi-sensor systems are being increasingly employed, some of which are also multi-modal. These systems may use sensors that are each of lower quality and lower cost, and may not be optimized for a given monitoring application; yet these multi-sensor systems may outperform a higher quality and higher cost individual sensor in terms of accuracy, robustness, and convenience. The rapid increase in biomedical monitoring has resulted in a large focus on “big data” in healthcare.

There has been considerable research and development effort in the acquisition of biomedical data and in data analytics to extract useful information from these data. In many acquisition systems, validation of the data in terms of quality typically requires a human. In data analytics, it is often assumed that data are of adequate quality for processing. When data are not of sufficient quality, this can result in erroneous conclusions including false alarms. For the fourth year in a row, the Emergency Care Research Institute (ECRI) identified alarm hazards as the top health technology hazard.

There is a pressing need for increased research on biomedical signal quality analysis. Biomedical signal quality analysis can be organized into four categories: 1) detection, observing the presence of contaminants in the signal, 2) identification, identifying the type of contaminant(s), 3) quantification, estimating the level of contamination, and 4) mitigation, removing or reducing the contamination. In some applications, simple detection may suffice, requiring only the ability to reject poor quality data. For non-expert users, identification of the contaminant type could be useful in providing feedback to remedy the acquisition setup. Biomedical signal quality analysis poses a variety of challenges, including large signal variability (inter- and intra-subject), contaminants that overlap in time and frequency with the signal of interest, and often a low prevalence of clinically significant events.
SP007.2 - Adaptive filter for eliminating baseline wander of pulse wave signals
**Author(s):** Aleksandr A. Fedotov, Anna S. Akulova
Lasers And Bioengineering Systems, Samara State Aerospace University, Samara/RUSSIAN FEDERATION

Recording and processing of arterial pulse signals are widely used in cardiology instrumental diagnostic systems. The arterial pulse signals are corrupted by physical and physiological interferences. Physiological interferences are happened due to the patient’s breathing and the effect of neurohumoral regulation factors and also the presence of low-frequency movement artifacts; these factors lead to the appearance of baseline wander: a nearly periodic low-frequency distortion of random nature. The stochastic nature of baseline drift in biomedical signals and also its broadband nature are the main reasons why new advanced methods should be developed for digital processing of the arterial pulse signal. In this article different baseline wander filtering methods were examined for pulse wave signal. A baseline drift correction method based on generating the reference signal of adaptive filter by using multi-resolution wavelet analysis of the original biosignal was proposed. This approach makes it possible to achieve the least distortions in processing pulse wave compared with other methods of eliminating baseline drifts. The effectiveness of proposed method, as well as other widely used approaches for filtering pulse wave signals such as approximation method, linear frequency filtering was studied.

Fig. 1 shows the fragment of arterial pulse signal with typical baseline wander (a); obtained estimation of the baseline wander (b); the pulse wave signal after application the new method of correction baseline wander proposed in this article (c).

![Graph showing baseline wander and correction](image)

SP007.3 - Efficacy of DWT denoising in the removal of power line interference and the effect on morphological distortion of underlying atrial fibrillatory waves in AF-ECG
**Author(s):** Jonathan Goodfellow1, Omar J. Escalon2, Vivek Kodoth, Ganesh Manoharan2
1Engineering Research Institute, Ulster University, Newtownabbey/UNITED KINGDOM, 2The Heart Centre, Royal Victoria Hospital, Belfast/UNITED KINGDOM

**Introduction:** Power line interference (50Hz) is a corruptive noise source which is commonly encountered when capturing body surface ECG signals. The purpose of this research is to assess the efficacy of Discrete Wavelet Transform (DWT) in removing mains noise by testing over thirty different wavelet functions. The four best performing wavelets were then further analysed to assess their effects on underlying fibrillatory waves which are present in atrial fibrillation patients.

**Methods:** 18 body surface ECG recordings of 1 kHz sampling frequency, which were corrupted by a range of mains interference levels (-10dB to 10dB) were simulated in MATLAB using an ECGSYN programme from PhysioNet. These signals then underwent a DWT denoising process which included 10-level decomposition, with full band cancellation of coefficients D1-D4, resulting in a significant attenuation of the added mains interference. The efficacy of the DWT denoising performance was assessed across the entire range of analysing wavelets and also compared to that of notch filtering, a technique which is widely used for mains interference suppression. The results were quantified and compared using three different performance parameters: Signal to Noise Ratio (SNR), Mean Square Error (MSE) and Signal Correlation Value (SCV). Additionally, we wanted to investigate the effect that the top performing wavelets would have on underlying fibrillatory waves which are present in atrial fibrillation electrocardiogram (AF-ECG), as certain key parameters of such waves have been shown to be useful in the characterisation and treatment of the arrhythmia. Five fibrillatory wave signals were extracted from real AF-ECG data using an average template subtraction method and were added to a range of mains corrupted simulated ECG signals. These signals were denoised using the top four performing wavelets and the underlying fibrillatory wave signal was recovered via the subtraction of the original ‘clean’ simulated ECG signal. Key parameters such as dominant frequency (DF) and total spectral power (TSP) of both the original and recovered fibrillatory wave signals were quantified and compared in order to assess whether or not the DWT denoising process was detrimental to fibrillatory wave characteristics.

**Results:** 12 out of 32 of the analysing wavelets tested outperformed a traditional notch filtering approach over all three performance indicators: SNR, MSE and SCV when averaged across the sample population. Four of the top performing wavelets were Daubechies ‘Db10’, Biorthogonal ‘Bior6.8’, DMeyer ‘Dmey’ and Symlet ‘Sym8’, with Db10 providing SNR, MSE and SCV values of 32.50, 5.13x10-5 and 0.9995 respectively. Fibrillatory waves were minimally affected by DWT processing with a 0% difference in DF and a 0.17% ± 0.25% difference in TSP across the study population.

**Conclusions:** DWT denoising can be an effective tool in the removal of unwanted 50Hz mains noise, where a range of analysing wavelets provide superior denoising performance when compared to traditional notch filtering. The process of DWT mains noise removal has negligible effects on the morphology or signal characteristics of underlying fibrillatory waves found in AF-ECG signals.

SP007.4 - Quantifying Blood-Oxygen Saturation Measurement Error in Motion Contaminated Pulse Oximetry Signals
**Author(s):** Geoffrey Clarke, Adrian D.C. Chan, Andy Adler
Systems And Computer Engineering, Carleton University, Ottawa/Canada

Oxygen saturation measurements from pulse oximetry (SpO2) can be unreliable in the presence of motion artifacts. While pulse oximetry is a crucial measurement in controlled environments, such as surgery or intensive care, its vulnerability to motion artifacts has slowed its adoption in wearable continuous monitoring devices. Measurement error can cause errors or delays in clinical decision-making. In remote monitoring applications, pulse oximeters should report measurement confidence along with SpO2 to help clinicians make decisions about the validity of alarm conditions. This paper seeks to relate signal quality to SpO2 measurement confidence.

In this study, clean photoplethysmograph (PPG) signals were collected from a pulse oximeter and contaminated with motion artifact. A range of linear combinations of signal and artifact were generated from collected SpO2 measurements. Two models based on Additive White Gaussian Noise (AWGN) were evaluated for their similarity to the motion artifact data. The first had identical noise on both red and infrared PPG signals; the second has uncorrelated noise. Both models successfully predicted negative measurement bias at low SNR, but only the second predicted the observed measurement variance.

![Graph showing SpO2 measurements](image)
Ambulatory electrocardiograms (ECG) can be used to monitor patients for myocardial ischemia. Low ECG signal quality, due to contaminants such as motion artifact, can lead to an increase in false alarms leading to alarm fatigue. The false alarms can be reduced by processing only ECGs of adequate quality, quantified by a signal quality index (SQI); contaminated ECG may be discarded. Four SQIs based on an estimate of the signal-to-noise ratio (SNR) were examined, where the mean, median, 25th percentile and minimum SNR were considered. ECG test data were retrieved from Physionet’s Long-Term ST Database; 30 minute segment of ischemic data and 30 minute segment of non-ischemic data were chosen from the record ‘s20031’. The record is sampled at 250 Hz and has a total of 2 unidentified leads. The SQIs were validated by contaminating 30 second segments of the ECG data with 30 seconds of motion artifact segments scaled at five levels from the record ‘em’ from the Physionet’s Noise Stress Test Database. The result is five copies of each ECG segment each with different calibrated SNR evenly distributed between -10 dB and 10 dB in steps of 5. For each channel of both the non-ischemic and ischemic data of the ‘s20031’ record, 300 segments were created, resulting in a total of 1,200 segments. Four SQIs were then generated for each of these 1,200 segments. The SQIs of each segment were compared to the calibrated SNR of both the non-ischemic and ischemic data of the ‘s20031’ record, and 30 minute segment of non-ischemic data were chosen from the record ‘s20031’. The record is sampled at 250 Hz and has a total of 2 unidentified leads. The SQIs were validated by contaminating 30 second segments of the ECG data with 30 seconds of motion artifact segments scaled at five levels from the record ‘em’ from the Physionet’s Noise Stress Test Database. The result is five copies of each ECG segment each with different calibrated SNR evenly distributed between -10 dB and 10 dB in steps of 5. For each channel of both the non-ischemic and ischemic data of the ‘s20031’ record, 300 segments were created, resulting in a total of 1,200 segments. Four SQIs were then generated for each of these 1,200 segments. The SQIs of each segment were compared to the calibrated SNR of the segment. A Pearson correlation coefficient was calculated between the SQIs and the calibrated SNRs for each of the cases (Fig. 1).

![Fig. 1 calculated Pearson correlation coefficient for SQIs and the calibrated SNRs for non-ischemic and ischemic data for channels 1 and 2](image)

It was found that a strong correlation (Pearson correlation coefficient $> 0.85$) was exhibited between the SQIs and the calibrated SNR for each segment with SQI based on 25th percentile exhibiting highest correlation. The strong correlation indicates that the SQIs are good representatives of signal quality.

SP007.6 - A simple algorithm for identifying artifact beats in long ECG recordings

**Author(s):** Nini Ran, Yongli Wan, Yang Yang, Ying Zhang, Jie Zhen, Sang Li

**Dept.** Of Biomedical Engineering, University of Electronic Science and Technology of China, Chengdu/CHINA

**Introduction**

The artifact beats in ECG recordings make diagnosis and monitoring of heart disease difficult and will increase the misdiagnosis rate. Clinically, it is time-consuming and labor-intensive to identify the artifact beats from long ECG recordings. Thus, there is a great need for developing an algorithm to automatically detect the ECG artifacts.

**Data**

The simulation data is used to determine the parameters in the algorithm. The independent data is the combinations of real ECGs of normal patients and patients with arrhythmia (such as atrial fibrillation, atrial flutter, ventricular premature beat, etc.) and the measured signals under the case of electrode loss. The sampling frequency is 250Hz and the total length is 2394.58s, in which there are the six segments of artifacts and the eleven segments of ECGs, in total 167.60s and 2226.98s respectively.

**Algorithm**

For a given ECG segment with the length of $L_s$, the three steps are carried out to identify its type using the novel algorithm.

**Step1:** Calculating the standard deviations of R-R interval (RRI) and R-peak amplitude in this ECG segment. If both parameters are synchronously greater than the two given thresholds (denoted by $ThrRR$ and $ThrRA$), the segment is judged as ECG artifact beats. Otherwise, go to the next step.

**Step2:** The ECG segment between 0.3*RRI at each R-peak before and 0.6*RRI at the R-peak after is selected as a template. If the length of a template is less than 100ms, the template is replaced by ECG segment of 700ms starting from 0.3*RRI at this R-peak before. The aim is to ensure each template contains at least three heartbeat cycles for detecting the rhythm.

**Step3:** The shift correlation is calculated between the given ECG segment and the template and the correlation function $r(i)$, $i=1,2,3,\ldots, L$ is obtained. The periodic wave peaks in the $r(i)$ can be used to reveal the rhythm of the ECG segment. Since the probability that three continuous wave peaks appears in $r(i)$ for the ECG artifacts is very small, the amplitude of the third wave peak of $r(i)$ is selected as the feature parameter discriminating the rhythm of the ECG segment. If this parameter is less than the given threshold (denoted by $Thrmax$), the ECG segment is identified as artifacts.

**Results**

When the $ThrRR$, $ThrRA$ and $Thrmax$ are set as 20, 10 and 0.75 respectively, the performance of the algorithm reaches optimal on the training data. The accuracy, sensitivity and positive prediction value of the algorithm on the independent data are 97.16%, 92.24%, 73.76% respectively, which are better than other related methods on the same data.

**Conclusions**

The logical structure and the computational complexity of the algorithm are simple and low respectively. The algorithm is sensitive to the artifact beats since of high sensitivity. Thus, it is suitable to be applied in the identification of artifact beats in long ECG recordings.
SP007.7 - Automatic Detection of Low-Quality Seismocardiogram Cycles Using the Outlier Approach  
Author(s): Vahid Zakeri1, Farzad Khosrow-Khavar2, Kouhyar Tavakolian3  
1Heart Force Medical Inc., Vancouver/BC/CANADA, 2Engineering Science, Simon Fraser University, Burnaby/BC/CANADA, 3Electrical Engineering, University of North Dakota, Grand Forks/ND/UNITED STATES OF AMERICA

In this study, an algorithm was developed to automatically detect the low-quality (LQ) cardiac cycles in seismocardiogram (SCG). The proposed algorithm extracts some features from the SCG signal, which are referred to as signal quality indices (SQIs), and computes the outlier points of each SQI. Our hypothesis was that the identified cycles (outliers) would include the LQ ones. To verify this hypothesis, the algorithm results were compared with the LQ cycles that were labeled manually by an expert in the field. The developed algorithm was tested on total 1697 cardiac cycles, and there was a great overlap between the computed outliers and the LQ cycles (84% of 248 LQ cycles were identified). The proposed algorithm is simple, efficient, and works in an unsupervised manner.

SP008 - Spinal Cord and Brain Injury Treatment  
TRACK 10: REHABILITATION MEDICINE, SPORTS MEDICINE, REHABILITATION ENGINEERING AND PROSTHESES

SP008.1 - A Validation Test of a Simple Method of Stride Length Measurement Only with Inertial Sensors and a Preliminary Test in FES-assisted Hemiplegic Gait  
Author(s): Takashi Watanabe1, Tasuku Miyazawa2  
1Graduate School Of Biomedical Engineering, Tohoku University, Sendai/JAPAN, 2Graduate School of Engineering, Tohoku University, Sendai/JAPAN

This study aimed to realize simplified gait evaluation system only using inertial sensors in order to support motor rehabilitation, healthcare and so on. In this paper, stride length measurement only with inertial sensors for the simple gait evaluation system was tested. First, a calculation method of the stride length was developed, in which acceleration and angular velocity signals of the foot were used. In order to calculate the stride length, the beginning and the ending of the foot movement during walking were detected by acceleration signal for determination of the integration period of motion acceleration of the foot. The motion acceleration was calculated from acceleration and angular velocity signals. The measurement method was evaluated in 10 m walking of 6 neurologically intact subjects attaching inertial sensors using stretchable band on their feet (shoes). Reference data for the stride were measured with portable walkways with embedded, pressure-sensitive sensors. The average values of error and absolute error of measured stride lengths were 0.38±4.77% and 3.36±3.04%, respectively. Correlation coefficient of the measured length with the reference data was 0.910 and the slope of the regression equation was 0.978. Then, stride lengths of a hemiplegic subject were measured in 10 m walking with and without FES-assisted foot drop correction. Although there was no difference in stride length between with and without the FES-assist, the calculated data from inertial sensor signals supported that the time for 10 m walking measured by therapists decreased when the subject walked with the FES-assist. It was expected that the stride length measurement only with inertial sensor would be practical, and it can be implemented easily.
SP008.2 - A novel Treadmill Body Weight Support system using Pneumatic Artificial Muscle actuators: a comparison between active Body Weight Support system and counter weight system

**Author(s):** Thuc V. Tran, Flavio Praticcio, Shin-Ichiroh Yamamoto

**Abstract:** In recent years, Treadmill Body Weight Support System has been developed and proved the improvement for patients who recover from Spinal Cord Injury. Passive and dynamic systems were shown their capacities to maintain unloading force in the vertical direction, however, there are no system considered that track the moving of the Center of Pressure trajectory during gait training. Our hypothesis is that tracking Center of Pressure trajectory, during gait training, could be more effective than the common system. This paper proposed a new active Body Weight Support system using Pneumatic Artificial Muscle actuators. An active model of new Body Weight Support system with the tracking model of the human center of pressure was developed. The validation tests experiments were implemented with three levels of unloading force 30%, 50% and 70% using new Body Weight Support system and counter weight system for comparison. The speed of the treadmill is set, for all the experiments at 2 km/h. Center of pressure trajectories are recorded for a normal random walk, for the counter weight system and for the Body Weight Support systems. The results showed that the center of pressure trajectory using active system was much fitter with center of pressure pattern of normal gait than counter weight system.

SP008.3 - A Serious Game for Training and Evaluating the Balance of Hemiparetic Stroke Patients

**Author(s):** Pedro Bertemes-Filho, Fabricio Noveletto, Antonio V. Soares, Marcelo D.S. Hounsell

**Abstract:** Stroke is the major cause of disabilities in adults and the second major cause of deaths worldwide. People that survive a stroke present deficits that affect their functional capacities and require rehabilitation for long periods. The use of digital entertaining games has shown to be a helping ally to the rehabilitation process, despite its therapeutic limitations. An alternative to these limitations is the development of games and control interfaces targeted the needs of patients, the so called Serious Games. The aim of this paper is to present the development of a Serious Game for training and evaluation of balance in hemiparetic stroke patients. An integrated biomedical system was, which consists of a balance board with inertial sensors instrumentation and a computer system that runs the game. The aim of the game, called myBalance, is to direct a ball to a target position according to the board signals. Various parameters of the game can be adjusted to comply with patients’ limitations. The game has a scoring system that extracts metric information regarding patients’ performance during gaming. Preliminary results indicate that the system (board and game) can be easily used for training and evaluation of patients’ balance. It was also showed that the game can be used as a metric system for clinical studies. Future works include comparing game scores to standard clinical scales for balance.

SP008.4 - fNIRS-based analysis of brain activation with knee extension induced by functional electrical stimulation

**Author(s):** Misato Ohdaira, Tomoko Kamisawa, Soichiro Morishita, Yinlai Jiang, Osamu Yamamura, Hiroshi Yokoi

**Abstract:** Patients suffering from paralysis due to aging, accidents, or brain injuries are increasing worldwide. Consequently, there is a compelling need for effective methods for the recovery of motor functions. The involvement of brain plasticity has been suggested effective and previous studies have reported that lost motor function and efficiency due to brain damage can be regained by repeatedly increasing and decreasing brain activation. Functional electrical stimulation (FES) has shown its effectiveness in the recovery of motor function. Brain activity usually decreases with the improvement of muscle control by FES. This study investigated the general ability of brain responses during rehabilitation with FES in order to elucidate the recovery mechanism. We monitored the brain activity of one healthy subject with fNIRS over a ten-day period (one experiment per day) during which the knee joint movement was induced by FES with different parameters. The subject was seated in the chair of a leg extension device (Fig.1). The measurement regions covered the primary motor cortex and the somatosensory cortex with transmitters and receivers shown in the right of Fig. 1. Receiver No. 5 in Fig. 1 was positioned on the Cz of the international 10-20 system. We stimulated his left quadriceps muscle with the FES device for 4 seconds. The results suggest that the observed increases and decreases of brain activity induced by FES are common (Fig.2). It is suggested that increasing and decreasing brain activation was evoked by long-term FES stimulation. Further research is needed to examine greater numbers of healthy subjects and patients suffering from paralysis to determine the optimum stimulation parameters for brain activation to involve brain plasticity.
Two healthy volunteers participated in a 4-hr experiment. Stimula

tion pulse, resulting in the need of unnaturally high stimula-
tion frequencies result in rapid fatigue, negatively impacting benefits
of stimulation rehabilitation. To address this issue, researchers have
“spatially distributed” and “sequentially” interleaved stimulation
pulses between multiple active electrodes (Spatially-Distributed-Se-
quential-Stimulation; SDSS; Figure 1A). SDSS allows muscle fibres
to be activated in an asynchronous manner, reducing the stimula-
tion frequency at each active electrode, while maintaining activation
of the muscle as a whole (Figure 1B). Although SDSS can improve
fatigue-resistance of isometric contractions, this method has not
been tested during non-isometric conditions.

Purpose:
To reproduce previous findings that SDSS can improve fatigue-re-
sistance of isometric contractions, and to extend this line of inquiry
to isokinetic conditions.

Methods:
Two healthy volunteers participated in a 4-hr experiment. Stimula-
tion (40 Hz; 0.3-s-on:0.7-s-off; 120-s total) was delivered to the
knee-extensors using SES and SDSS, in separate trials, to generate
isometric (0°/s) and isokinetic (180°/s) torque. Isometric and iso-
kinetic contractions were tested on separate legs in separate trials.
A rest period of 2-hr was provided between repeated testing of each
leg. Protocol order was randomized. Stimulation intensity was set to
generate ~40% maximum-voluntary-contraction.

Results:
Fatigue indices were calculated (final torque/initial torque) for iso-
metric (SES=0.37; SDSS=0.57; Figure 1C) and isokinetic (SES=0.36;
SDSS=0.39; Figure 1D) contractions.

Conclusion:
Previous findings that SDSS can improve fatigue-resistance of iso-
metric contractions were reproduced. However, the effect of SDSS
on improving fatigue-resistance may not be as pronounced during
isokinetic, compared with isometric, contractions.
SP008.7 - Motor Control Assessment using Leap Motion: Filtering Methods and Performance in Indoor and Outdoor Environments
Author(s): Jong J. Kim1, Dave A. Gonzalez2, Adam Mintz2, Eric A. Roy2, James Y. Tung3
1Mechanical And Mechatronics Engineering, University of Waterloo, Waterloo/CANADA, 2Kinesiology, University of Waterloo, Waterloo/CANADA

In this paper, we describe and evaluate a filtering method designed to remove the artifacts from hand/finger kinematics acquired using the Leap Motion controller (or ‘Leap’). We report two experiments evaluating this methods: 1) accuracy and precision compared to an established motion-tracking system (Optotrack) and 2) performance in indoor and outdoor environmental conditions. The main findings were that the filtered Leap finger output: i) compared well to motion capture systems in temporal accuracy and precision, ii) moderately well in spatial accuracy and precision, and iii) adequately in indoor settings, but not in outdoor conditions. These advances will inform further development of new tools to assess human motor control.

SP008.8 - Biceps brachii EMG signals: estimation of dipole sources
Author(s): Peyman Aghajamaliaval1, Pierre A. Mathieu2, Mickael Corinthios1, Michel Bertrand2, Jean Laurier2
1Génie électrique, École Polytechnique, Montréal/CANADA, 2Physiologie Moléculaire Et Intégrative, Institut de génie biomedical, Montréal/QC/CANADA

The biceps brachii (BB) was shown to be anatomically composed of up to 6 innervated compartments from which as many independent electromyographic (EMG) signal sources could be obtained. Extracting several signals from a single muscle would allow upper-limb amputees to produce several forearm/hand movements with a myoelectric prosthesis. While normal subjects were either sitting or standing-up, we investigated how to activate those compartments by using various right upper limb and hand positions. Five pairs of surface electrodes were put across the short head (SH) and 5 others pairs over the long head (LH) of the BB. Five seconds EMG signals were recorded during isometric contractions produced at a constant level. RMS value of each signal was obtained.

EMG signals where assumed to originate from dipole sources within the arm. A peel-off method served to search for up to 6 dipoles which were used as moving sources in a 3-D finite element forward model study (COMSOL). Arm was modeled either as a single or as 4 concentric cylinders (for skin, subcutaneous fat, muscle and humerus). Comparison was made between amplitude of the simulated and experimental signals.

Results for one seated subject are shown in Fig. 1. In column A, there are significant amplitude differences between some of the experimental signals and model predicted values. Differences were reduced in a second iteration during which dipole parameters are readjusted (column B). With a 4 layers model (column C), differences can be larger and it is also observed that some dipole positions are physiologically incorrect (i.e. in the fat layer). So, while the peel-off method provides a first estimate of the dipoles characteristics, the 4 layers model is necessary to do the proper dipoles readjustments that constrain the position of the dipoles to the muscular tissue.

SP008.9 - Validating a Solid-Static Single-Armed Male Prototype Tasked to Produce Dynamic Movement from the Shoulder Through the Preparation Phase
Author(s): Alicia M. Gal1, Adrian D.C. Chan1, Dean C. Hay2
1Computer System Engineering, Ottawa Carleton Institute for Biomedical Engineering, Ottawa/CANADA, 2Physical And Health Education, Nipissing University, North Bay/CANADA

The purpose of this study was to design, implement, and validate a methodology to determine baseline measures during the preparation phase (PREP) of seated weight-bearing locomotion. In order to evaluate this methodology this study investigated the external movement produced by the shoulder joint-centre of the upper limb through a seated downward poling motion. A solid-static anatomically correct prototype was designed to produce isolated dynamic movement about a human’s shoulder joint-centre; this particular investigation replicated the average male weighing 80kg having fixed elbow (135°) and wrist-stick (45°) angles, and dynamic shoulder start angles (-10°, 0°and +10° to the horizon). The prototype was tasked to produce PREP; a phase identified in seated locomotion produced through a double poling fashion. Trajectory and reaction forces created through PREP were evaluated using a standard Newton-Euler mathematical model in conjunction with a 3-dimensional motion capture system and force plate. Trajectory data concluded that the prototype was of reliable and valid mechanical design producing near identical curves for all trials individually as well as combined averages. Evidence also indicated that all trials displayed similar reaction forces, which produced torque in an anticlockwise direction about the shoulder. Since the prototype is solid and designed to mimic the male upper limb data can be used to describe minimal reaction forces onto the shoulder joint produced from PREP. Understanding external forces at baseline measures allows for valid assumptions to be made or dismissed concerning internal forces within the human body. Dynamic biomechanical analysis requires assumptions involving internal and external parameters when producing a movement. The addition of PREP to the seated propulsion cycle is unclear identifying the need to investigate the biomechanics produced through this phase; full arm extension to pick-plant. This study has developed an improved model of the upper limb during seated double poling.
SP009 - Patient Safety, Medical Errors and Adverse Events Prevention Related to Health Technologies and Incident Analysis and Management

SP009.1 - Technological Surveillance and Integrity Monitoring of Infusion Systems
Author(s): David Grosse-Wentrup, Uvo M. Hoelscher
Center For Biomedical Engineering And Ergonomics, Münster University of Applied Sciences, Steinfurt/GERMANY

Infusion therapy is a routine medical procedure. As errors can have potentially fatal consequences, monitoring of infusion systems is mandatory. At present, the technical monitoring of infusions is limited to only a few properties of the infusion system. This passes the demand for vigilance on to the clinical personnel and potentially leaves errors undetected.

By sending small pressure pulses through the interconnected infusion lines, a route map of the infusion system can be created. This map visualizes the connections of infusion lines including line lengths, connection points and connected infusion devices.

This way, errors in the infusion system setup, loosened connections, erroneous stopcock positions and thereby caused under-infusion or reflux can be automatically detected, indicated to clinical personnel, and subsequently corrected before causing harm to the patient.

SP009.2 - Evaluating Patient Safety Risks Related to Oral Chemotherapy: Evolution of a Human Factors Informed Failure Mode and Effects Analysis Framework
Author(s): Melissa Griffin1, Rachel Gilbert1, Larry Broadfield2, Andrea Cassano-Piche3, Anthony Easty1, Patricia Trbovich1,1Centre For Global Ehealth Innovation, University Health Network, Toronto/ON/CANADA, 2Cancer Care Nova Scotia, Halifax/CANADA, 3ibbme, University of Toronto, Toronto/CANADA

Chemotherapy is commonly used to treat cancer, which is the leading cause of death in Canada (PHAC, 2012). Chemotherapy treatment involves the use of complicated and flexible drug protocols to care for patients experiencing different types and stages of cancer. A variety of healthcare professionals, who practice in different locations, are involved in the delivery of chemotherapy. Traditionally, most intravenous (IV) chemotherapy is administered to patients in hospital settings, but more recently oral chemotherapy is being delivered in the home and community. Many patients, families, and providers prefer oral to IV chemotherapy for several reasons, including its perceived convenience (Liu, 1997). Manufacturers are facilitating this shift, with an estimated 25% of the 400 new medications currently in development being formulated as oral medications (NCCN, 2008).

IV and oral chemotherapy have comparable toxicity risks and the potential to cause serious harm when not managed properly. However, oral chemotherapy is associated with some unique challenges, such as access, adherence, and safe handling. Many of these challenges stem from a shift in responsibility for administering chemotherapy from healthcare professionals to patients and their families. With increased attention being paid to oral chemotherapy safety (Neuss, 2013), a Canadian provincial cancer agency approached HumanEra, a team comprised of human factors specialists, to analyze their current practices and identify any risks and opportunities related to oral chemotherapy from a human factors perspective.

Two human factors specialists collected field data using direct observations and semi-structured interviews. Healthcare professionals involved in providing patients with chemotherapy, such as staff in the cancer centre clinics and pharmacy, as well as a number of community pharmacies, were included during data collection. Process maps were created to describe chemotherapy-related processes from when lab work was done through to when chemotherapy was dispensed in the community.

Data were analyzed using a human factors informed failure mode and effects analysis (HF/FMEA) framework. This framework was developed iteratively, and is also presented in the upcoming Human Factors for Health Technology Safety book (Cassano-Piché, et al, in preparation). Unlike more traditional FMEA frameworks, the HF/FMEA framework guiding this assessment included three tests: the severity test, the hazard score test, and the single point weakness test; to prioritize which key failure modes to focus on for the remainder of the analysis, making the analysis more efficient. Using this framework, a total of 201 failure modes were identified, with 73% of those being key failure modes requiring further analysis. Although 147 failure modes were still prioritized as key failure modes requiring further attention and analysis (e.g., patient removes the incorrect number of pills from their bottle), the HF/FMEA framework allowed 54 failure modes to be set aside before time was invested identifying causes and recommendations for these lower priority risks (e.g., pharmacy assistant does not pick chemotherapy drug from shelf).

This presentation will provide an overview of the HF/FMEA framework and highlight results from applying this framework to oral chemotherapy processes in a Canadian province, to demonstrate how HF/FMEA can be used to improve healthcare safety.

SP009.3 - Alarm Management Study in Pediatric Special Care Unit
Author(s): Christopher J. Bzovey1, Paul Prowse2
1Clinical Engineering, Winnipeg Regional Health Authority, Winnipeg/MB/CANADA, 2Clinical Engineering, Winnipeg Regional Health Authority, Winnipeg/CANADA

There have been a number of critical incidents reported where improperly managed alarms contribute to alarm fatigue in clinicians resulting in patient harm or mortality. Numerous studies have been published in the United States; however there appears to be a lack of publications on alarm management investigation studies conducted within Canada.

The purpose of this work was to investigate the current state of alarm communication and management within the Pediatric Special Care Unit (PSCU). The investigation included an environmental assessment, a staff survey, and a review of the alarm event logs from several medical devices. The staff survey investigated current alarm management practices by analyzing self-reported effects of alarm fatigue experienced in the PSCU. The survey identified ventilators and patient monitors as most heavily contributing to alarm load. Alarm logs were collected from those devices.

The environmental assessment revealed that ventilators within the unit are connected to a latching nurse call system, which requires staff intervention to reset. Within 30-40 seconds after alarming, the alarm increases in volume and pitch resulting in greater distress for the staff and patients within the unit. The staff survey identified that the alarm load they experience has a moderate to high effect on their ability to provide safe patient care (Figure 1). Data collected from the patient monitors demonstrated a significant difference between the number of alarms during the day and night shifts (Figure 2).
and severity for each step. Results of the application of FMEA for the major process “treatment planning” are reported here. Hazard index given by the Risk Priority Number (RPN) is found to range from 4 - 270 for various processes and the severity (S) index is found to range from 1 - 10. The RPN values > 100 and severity value ≥ 7 were chosen to flag safety improvement interventions. Number of steps with RPN >100 were found to be 6, 45 and 59 for the three centers. The corresponding values for S ≥ 7 are 24, 21 and 25 respectively. The range of RPN and S values for each center belong to different process steps and failure modes (see table).

These results show that interventions to improve safety is different for each center and it is associated with the skill level of the professional team as well as the technology used to provide radiosurgery treatment. The present study will very likely be a model for implementation of risk-based prospective quality management program for SRS treatment in Brazil where currently there are 28 radiotherapy centers performing SRS. A complete FMEA for SRS for these three radiotherapy centers is currently under development.

This work demonstrates that alarm load is a problem in the PSCU, and furthermore the intensity is dependent on the time of day. A committee has been established to discuss potential solutions for mitigating the alarm load. The success of this will be discussed during the presentation.

**SP009.4 - Failure Modes and Effect Analysis for Stereotactic Radiosurgery: a comparison among three radiotherapy centers in Brazil.**

**Author(s):** Flavia Cristina S. Teixeira, Carlos E. Dealmeida, Mohammad S. Huq
Lcr, LCR/UERJ, Rio de Janeiro/BRAZIL

Task Group 100 of the American Association of Physicists in Medicine recommended the adoption of prospective quality management techniques such as process mapping, failure modes and effects analysis (FMEA) and fault tree analysis (FTA) for analyzing clinical processes and for designing clinic- and site-specific quality management programs that are based on risk assessment. According to this approach, each facility determines the hazards and risks at their own facility based on their own processes and procedures. Appropriate quality control measures are then put in place to mitigate the risks associated with a given process. The goal of the present work was to evaluate the process maps for stereotactic radiosurgery (SRS) treatment at three radiotherapy centers in Brazil and apply the FMEA technique to evaluate similarities and differences, if any, of the hazards and risks associated with these processes. A team, consisting of professionals from different disciplines and involved in the SRS treatment, was formed at each center. Each team was responsible for the development of the process map, and performance of FMEA and FTA. A facilitator knowledgeable in these techniques led the work at each center. The TG100 recommended scales were used for the evaluation of hazard
SP010 - Biomedical Engineering in Nigeria: A Developmental Overview

Author(s): Kenneth I. Nkuma-Udah, Gideon I. Ndubuka, Kennedy O. Ejeta
Department Of Biomedical Technology, Federal University of Technology, Owerri, Nigeria, Owerri/NIGERIA

Biomedical Engineering (BME) activities in Nigeria can be said to have started in the 1970s during which collaborative efforts were made by engineers, medical doctors, pharmacists, physicists, technicians and other scientists. Although, the pace of development was hitherto slow, most efforts were in the area of training - short courses, continuing education or professional development. However, the coming of NIBE in 1999 has propelled a steady progress of BME activities in Nigeria. This is rightly so, because Nigerian BME professionals from 1999 started addressing issues concerning them as a professional group. BME activities in Nigeria was further given a big boost in 2007, when the first undergraduate programme in BME started in the Federal University of Technology, Owerri, Nigeria with NIBE contributing the foundation members of faculty. NIBE, which stands for Nigerian Institute for Biomedical Engineering, represents the BME profession and its members in Nigeria and in international organisations. Established in 1999 with the vision “to develop and advance the biomedical science, health and human well-being of Nigeria through modern technological approaches comparable to those obtainable in any developed country of the world”, NIBE has members largely of the various sciences and classical engineering disciplines from universities and hospitals as well as from other institutions/organisations. It has a membership list of over 2000 members, but financially active membership fluctuates between 100 and 200 depending on the BME activity of each year. NIBE is currently structured in 5 divisions - biological engineering; medical engineering; clinical engineering; rehabilitation engineering; and biomedical physics / allied sciences - to accommodate virtually every field in the sciences. It has its 1st annual BME conference in 2000. Since then it has organised 9 national biomedical engineering conferences and 6 national professional development courses in Nigeria. NIBE has published a newsletter, news@nibe since 2000; a professional journal, Nigerian Journal of Biomedical Engineering since 2001; and electronic mail news, e-nibe since 2003. In 2003, NIBE was admitted as the 50th member of IFMBE. The same year, she co-founded the African Union of Biomedical Engineering and Sciences (AUBES) in Ghana while some members were on a Medical Equipment Training. AUBES was established in order to integrate the effort of various African BME professionals and to expand cooperation on a continental basis. Since 2003, NIBE has made effort with AUBES to pioneer the development of BME in Africa. AUBES’s official inauguration and the 1st African Biomedical Conference scheduled to hold in 2005 in Nigeria was cancelled for logistic reasons. However, sustained effort is being geared towards its official inauguration in 2016 in Nigeria. The role of NIBE in developing BME in Nigeria is mainly as a membership group to develop resources for BME by evolving adequate training programmes for members, facilitating accreditation and certification of professionals practicing BME in Nigeria. NIBE is expected to continue to give its members a sense of belonging by becoming the mouth piece of BME professionals in Nigeria. All these development efforts should be a matter of concern for the international BME community.
cases, the biomedical engineers are recruited from abroad to either consult or work as permanent employees. Three training centres in the country have started biomedical engineering training. ECUREI started a biomedical technician diploma before the Ministry of Health initiated a diploma training with Kyambogo University 3.5 years ago. This diploma is supported by the Amalthea trust from the UK. Makerere University started a degree programme 3.5 years ago. With all this training happening, the technicians and engineers job roles have not yet been included in a lot of government hospitals with pay scales a big challenge to many aspiring technicians and engineers in the field.

Methods
A sustainable volunteering project was developed to improve skills of technicians working in seven hospitals. None of the technicians chosen for the project had any formal training in medical equipment management but were routinely involved with the repairs. The main objectives were to improve the process of procurement, repair and disposal of medical equipment by benchmarking with UK and other international standards. A volunteer Biomedical Engineer was recruited from the UK to work as a trainer and provide in-house mentorship to the technician for over 2 years.

The project was in collaboration with the Amalthea trust who provided intensive two weeks training in each year through Kyambogo University. Different parties, including the Ministry of Health, Commercial medical equipment providers and the professional association were always involved throughout the duration of the project. The volunteer also contributed to lecturing and improving the degree programme at Makerere University. Collaboration was formed with the Uganda Industrial Research Institute to replicate the work in other hospitals.

Four technicians were taken to the UK through the commonwealth professional fellowship programme to gain more on job experience.

Results
The technicians showed improved skills, knowledge and confidence about medical equipment management. There has been increased awareness of biomedical engineering profession through workshops and conferences. Inventories were developed using Microsoft Excel and they have been updated yearly since the beginning of the project. There has been increased confidence in the technicians by the clinicians about them handling the medical equipment. The link for the biomedical engineering volunteer between the hospitals and Makerere University means that the students have easy access and can always get feedback from real life scenarios. Some hospitals have set up biomedical engineering workshops and recruited biomedical technicians as a direct result of the project.

SP010.4 - Designing Biomedical Engineering Programs to Prepare for Medtech Industry
Author(s): Shankar Krishnan
Biomedical Engineering, WIT, Boston/MA/UNITED STATES OF AMERICA

The astounding arrays of inventions, innovations and implementations of technologies have resulted in a huge growth in the medical devices and systems worldwide. Medtech industry is instrumental in manufacturing complex medical devices and systems. A vital role is played by Biomedical engineering (BME) in research and development by creating advances in applications of multidisciplinary technologies which ultimately traverse towards improved and efficient health care delivery, which generates consistently increasing demands for biomedical engineers at the international levels. Consequently, the needs for biomedical engineers trigger corresponding requirements for training biomedical engineers, especially for the medtech industry. The responsibility of developing academic programs to train students to gain multidisciplinary knowledge and adequate expertise in research, design, development, manufacturing, operations, compliance and regulatory affairs is bestowed on the academic leaders who face numerous challenges. The objective of this paper is to determine the challenges and present potential solutions in the design of undergraduate biomedical engineering programs to prepare the students for meeting the existing and emerging demands of medtech industry.

The duration of a typical undergraduate BME program is four years in most American Universities. Major challenges are encountered while designing a comprehensive undergraduate BME curriculum within the available duration. Essential factors including the breadth and depth of BME coverage, distribution of relevant theoretical and practical aspects, and, course work, laboratory work, project work knowledge and skillset to fulfill the graduation requirements, in conjunction with appropriate preparation for career paths, are to be considered diligently in the overall design of the BME program. Foundations in mathematics, sciences and engineering are vital prerequisites to the core courses in BME. For achieving superior student outcomes pertaining to conducting experiments and carrying out projects, well-equipped laboratories and faculty mentors with related academic and industrial experience are essential. Additionally, a cluster of elective BME courses catering to the existing and emerging needs of the industry and employers must be incorporated in the curriculum. The aforementioned factors pose strenuous challenges in the BME program design.

A few model designs of BME programs are developed to overcome the challenges cited above. The curricula for the proposed models are formulated employing general structure, track-based structure, and emphasis-based structure. A preferred model is based on emphasis of medical devices and systems in the curriculum coupled with embedded internship or co-operative experiential learning modules to prepare for employment in medtech industry. Real life experiential learning thru placement at a medtech industry or a teaching hospital undoubtedly complements the knowledge and competencies acquired on campus. BME program directors should make special efforts to recruit and retain dedicated faculty and technical staff. Continuing support of resources are necessary for the successful execution of the academic programs. The curricula for the proposed models have been developed in different academic settings and implemented. Extensive experience in designing and directing multiple models for BME undergraduate education lends support to the success of carefully designed site-specific programs to prepare the students for the medtech industry involving medical devices and systems.

SP010.5 - BME vs CE vs HTM vs HbHTA vs EAM. What's in a Name and does it matter?
Author(s): Maden A. Poluta
Human Biology (bme Division), University of Cape Town, Observatory/SOUTH AFRICA

Background:
Technology is increasingly an essential component of effective healthcare delivery in diverse settings. Ensuring that healthcare technologies are optimally planned, assessed, acquired, implemented, managed and replaced is a complex process involving many stakeholders and players. While the adage “Don’t fix what ain’t broke” applies in the context of established practices in different jurisdictions, it is nevertheless important to consider where we stand collectively. Greater alignment, clarity of purpose and standardisation - as well as a common future vision - would support stakeholder engagement, demystify guidance to countries (especially those that
are resource-challenged), support capacity building and facilitate both achievement of critical mass in diverse settings and mobilisation of resources for related activities. This paper provides one perspective of the status quo and makes some suggestions for the way forward, with a focus on engineering/technical disciplines related to healthcare technologies.

**Issues:**

How can we address the lack of uniformity in both nomenclature and practice? For example, BME is often seen as synonymous with CE, but not universally so, and both are referred to by other terms.

What are the generic international classifications pertaining to BME and CE? (Ref: ISCO-08)

How can recognition to be given to the full range of engineering professionals: engineers, technologists and technicians? (Ref: Washington-, Sydney- and Dublin Accords of the International Engineering Alliance)

How different is HTM from Clinical Engineering, and both HTM and CE from the emerging fields of Hospital-based HTA and Engineering Asset Management, respectively?

What are the individual ‘value-adds’ and focus/impact areas for BME, CE, HTM, HbHTA and EAM, and is there merit in unifying/aligning these disciplines?

Figure 1 below shows how the disciplines/specialities addressed could combine in serving a common purpose, while recognising their specific roles and contributions to the overall process.

**Figure 1:** Optimised Life-Cycle management of Healthcare technologies, showing the contribution of supporting disciplines, specialities and fields.

**SP010.6 - Clinical Engineering Certification Program in the Americas**

**Author(s):** Frank R. Painter
Biomedical Engineering, University of Connecticut, Trumbull/UNITED STATES OF AMERICA

The American College of Clinical Engineering’s (ACCE) definition of a clinical engineer is a professional who supports and advances patient care by applying engineering and managerial skills to healthcare technology. One of ACCE’s mission statements is to define a body of knowledge on which the profession is based. Using the definition and the information received from a body of knowledge survey sent to over 500 practicing clinical engineers from around the world, in 1990 a clinical engineering certification exam was created.

The Healthcare Technology Certification Commission (HTCC) was formed to oversee the process and a Board of Examiners was formed to create the exam and test the candidates. The financial aspects of the certification process are managed by ACCE on behalf of the HTCC.

After several years it became apparent that the process could be adopted by other countries. In 1995 the Canadian Board of Examiners was formed and the CCE exam became a collaborative process between the Canadian and US Board of Examiners. In the meantime collaboration with several countries in South and Central America as well as the Middle East has been discussed.

The exam process includes three major components; the application, written exam and oral exam. The application process consists of the simple application, university transcript and three professional references. Through this the candidate must demonstrate they have sufficient clinical engineering experience to qualify to take the exam. The exam consists of 150 multiple choice questions distributed across CE topics in the same proportion as they appear in the body of knowledge survey results. The oral exam is a structured exam questioning the candidate on three separate real life clinical engineering scenarios.

The Board of Examiners publish an application and a handbook to guide the candidate through the process. These are available on the certification page of the ACCE website (www.accnet.org). This page also includes information on the CCE renewal process, recommended resources for use in preparing for the exam and a list of those currently certified. 221 certified clinical engineers are currently listed.

**SP010.7 - Biomedical Technology Online Courses for the Americas**

**Author(s):** Tobey Clark1, Alexandre Lemgruber2, Francisco Caccao3, Tatiana Molina Velasquez4, Federico Gracia5, Rossana Rivas6, Luis Vilcahuaman6
1Instrumentation & Technical Services, University of Vermont, Burlington/UNITED STATES OF AMERICA, 2Health Technologies, Pan American Health Organization, Washington DC/UNITED STATES OF AMERICA, 3Universidad CES, Medellin/COLOMBIA, 4Universidad Tecnológica Nacional - Facultad Regional Mendoza, Mendoza/ARGENTINA, 5Health Technopole CENGETS PUCP, Lima/PERU, 6Bioengineering Laboratory, Bme Ms Program, Pontifical Catholic University of Peru, Lima/PERU

Latin America and the Caribbean countries are rapidly expanding their healthcare technology usage. Physicians, patients and their families are understanding better the relevant influence of healthcare technology based on clinical, ethical, social, and economic health outcomes. Companies are eager to expand to this growing area, and donations from developed countries of new and used equipment continue.

In general, the regional status of Latin American and Caribbean countries includes: little medical device regulations, a high percentage of devices that are out of service, weak after sale device support with nearly all service from manufacturers or their representatives, a shortage of technical staff in hospitals, very limited maintenance budget, inadequate number of healthcare staff appropriated trained and limited technology management.

What is needed is training and education of staff at the hospital level in the various technologies used in healthcare. Education and training of clinical and technical staff interacting with medical technology enhances the effectiveness and safety of medical care.

Through a grant from the PAHO Foundation (formerly PAHEF), biomedical technology online courses were developed for clinical and technical staff. Online training via the Internet allows 24x7 accesses to training resources in an asynchronous fashion. Extensive use of web resources and simulations enhance the courses. The course topics include anatomy/physiology, engineering concepts, physiological monitors, cardiac therapy devices, ventilators, infusion technology, all imaging modalities, surgical systems, clinical information networks, and therapy devices. The initial English version has been taught in the USA since 2007. The courses were translated to Spanish and adapted for use in Latin America for use in 2008. Over 1000 students from 28 countries have taken the courses at the University of Vermont USA, Universidad CES in Colombia, Universidad Tecnológica Nacional - Facultad Regional Mendoza in Argentina, and Pontificia Universidad Católica del Perú.

In September 2014, the online courses were placed on the PAHO...
Virtual Campus for Public Health. The PAHO Virtual Campus for Public Health with over 100 courses offered currently has students from over 140 institutions enrolled from the Americas. The PAHO platform allows a broader range of students from the Americas to enroll in the courses especially those without the funds for university courses. Forty-eight students from twenty-one countries enrolled in the twenty-four week English and Spanish courses – Introduction to Biomedical Technology. Course assessments and evaluation will be available following the end of course on April 24th and will be presented at the WC2015. Future plans are for translation of the courses to Portuguese and adaptation to Brazil, and additional educational offerings on healthcare technology planning and management.

SP011 - Overview of Gender Roles in Medical Physics in North America

TRACK 18: GENDER, SCIENCE AND TECHNOLOGY

SP011.1 - Gender, Science and Technology: The Role of Women in Medical Physics

Authors(s): Kristy K. Brock
Radiation Oncology, University of Michigan, Ann Arbor/MI/UNITED STATES OF AMERICA

The role of women in the field of medical physics has been steadily increasing over time. Data obtained from the AAPM shows that the women comprise an increasing percentage of the overall membership. In the late 1960s, less than 10% of the membership was female, however this has been steadily increasing and in 2014, 21% of the full membership is female and 29% of the overall membership (including student members) is female. If this trend continues at the same rate, by 2044 we would expect equal representation of males and females in the field. It is important to not only evaluate the membership, but also the engagement of women within the active membership and leadership positions within the field and professional society. AAPM staff assisted in mining the membership database for statistics on gender representation in the society membership, engagement in the AAPM, presentations at the annual AAPM meeting, and AAPM leadership. Full membership was used as the gender baseline as student members are not allowed to serve on committees, however they do present at the annual meeting. Engagement in the AAPM was classified as membership on an AAPM committee, which has the structure of 3 councils (Professional, Educational, and Science) under which there are several committees, subcommittees, working groups, and task groups. Presentations at the annual meeting were evaluated based on authorship, first author presenting a poster, first author presenting at the podium (oral), session moderators, invited speakers, and invited speakers in the educational, professional, and scientific track. Presentation data was obtained over the past 5 meetings (2009-2014). Leadership in the AAPM is defined as members of the Board of Directors (nominated by a committee and elected by the full membership or elected from a local chapter), membership on the Executive Committee (nominated by a committee and elected by the full membership), and President (nominated by a committee and elected by the full membership). Gender representation in distinguished awards given by the society was also evaluated.

Of the AAPM membership currently serving on a committee, working group, or task group, 21% are female, the same ratio of women in the AAPM membership. Further evaluation of ‘very active’ members, defined as membership in 5 or more committees, found that this representation is maintained, with 20% of very active members being female.

Evaluation of the past 10 AAPM annual meeting shows that of the over 60,000 authors of AAPM abstracts, 16% were female. 20% of the 6,794 poster presentations were given by women and 18% of 6,947 oral presentations were given by women. Abstracts acceptance and placement in a poster or oral session (highest scored abstracts) are based on single blind reviews (authors’ names are known to the reviewers). Session moderators are selected by the scientific program committee and of the 451 moderators over the past 10 years, 16% were female. The AAPM Meeting Coordination Committee invites speakers for educational, professional and scientific sessions. Over the past 10 years, 17% of the invited speakers in educations sessions have been female, 23% in the professional
The current Board of Directors for AAPM is comprised of 46 individuals, 10 of whom are female (22%). Historically, of the 18 Secretaries of the AAPM, 2 have been women (11%) and 7 of the 15 Treasurers have been women (47%). There have been 57 presidents of the AAPM society, 3 of whom have been women (5%). The first female president of the AAPM was in 1982, the last 2 in 2007 and 2009. Of the 897 awards bestowed by the AAPM, 9% have been awarded to women. The William D. Coolidge Award recognizes ‘an AAPM member for an eminent career in medical physics. It is the highest award given by the AAPM’ and has only been awarded to one woman, in 1977.

These trends show promising inclusion of women in medical physics. The increase in the number of women pursuing careers in medical physics is evident by the steady increase in the percentage of women making up the membership. It is encouraging to see that this rate of women entering the field is also matched by active engagement in the society (through membership on committees) and emerging in leadership, as seen in membership of the Board of Directors, however not yet matched at the presidential level.

Learning Objectives:

1. Highlight the role of women in Medical Physics.

2. Evaluate the engagement of women in the American Association of Physicists in Medicine.

3. Understand gender related issues in science and technology fields.

**SP011.2 - Biography of Women in Medical Physics: Maryellen Giger, Ph.D.**

**Author(s):** Maryellen L. Giger  
Radiology/medical Physics, University of Chicago, Chicago/UNITED STATES OF AMERICA

My brothers and I were first-generation college and were raised with the importance of education. Following the completion of my Bachelor’s Degree in Mathematics, Physics, and Health Sciences from the Illinois Benedictine College, I studied Physics at the University of Exeter, earning a Master’s Degree. This experience led me to the University of Chicago to study Medical Physics, where I earned my PhD in 1985. I continued my tenure at the University of Chicago becoming faculty in 1986 in the Department of Radiology. At the University of Chicago, I have served as Director of the Advanced Imaging Program in the Cancer Research Center, Director of our CAMPEP-accredited Graduate Program in Medical Physics, and Chair of the Committee on Medical Physics. I am currently the A. N. Pritzker Professor of Radiology/Medical Physics and Director of the BSD Imaging Research Institute at the University. My passion for medical physics began while working summers during college at Fermi National Laboratories where I assisted in the beam diagnostic group and the neutron therapy group. I have also served as President (and Chairman of the Board) of the American Association of Physicists in Medicine, Board member of SPIE, and Editor-in-Chief of the SPIE Journal of Medical Imaging. I am a Fellow of AAPM, AIMBE, and SPIE. I was honored to be elected to the National Academy of Engineering and to be named by the International Congress on Medical Physics as one of the 50 medical physicists with the most impact on the field in the last 50 years. I feel that my most significant scientific achievement was providing leading contributions to the field of computer-aided diagnosis. I have more than 170 peer-reviewed publications (over 300 publications), more than 20 patents, and mentored over 100 graduate students, residents, medical students, and undergraduate students. Also, my husband and I have raised our four children through various trips to AAPM, SPIE, and other scientific meetings. The best part of my “job” is when my student becomes a colleague. I look forward to sharing my experience at the World Congress.

**SP011.3 - My STEM story: from Martinique in the Caribbean to Quebec City, through France and Vietnam**

**Author(s):** Nadia Octave  
Radiation Oncology, CHU de Québec, Québec/QC/CANADA

It is always a bit intimidating to be asked to come forward to talk about one’s personal life, experiences and career path. Someone said stories can move people and inspire them. That is for big stories, I would say. My aim would be just to send seeds in the wind and who knows? May be one will bear fruits? So to start, I am a medical physicist born and raised in Martinique, a French region in the Caribbean. I have a biomedical engineering background with a master in medical technologies from Toulouse Paul Sabatier University, and a specialization in radiation physics and imaging. Two long-term internships in Toronto had a major impact on my following choices and did actually prove to influence all the rest of my career path until my current job position in Quebec City. But that is a long story that I cannot tell in a few words, because I would have to start with the very beginning: my thirst for knowledge of the human body and its biology and my first interest in physics with the moon and astronomy. To this I have to add, the meeting of important role models and mentors to whom I could always refer and who could share their own experiences with me. Also I could tell you about my years of training at the Curie Institute, at the Gustave Roussy Institute and my first position as a junior medical physicist at the Georges Pompidou European Hospital in Paris and also about an experience within the experience working in Vietnam. But more importantly I would like to emphasize on the challenges and obstacles that I overcame. I will also share some strategies that worked for me so that you too can be convinced that the only limits are the ones that we imposed to ourselves. And finally, since stories without actions are meaningless, I will speak about an initiative here today.

**SP011.4 - My strategies for living (and enjoying) academic research**

**Author(s):** Rebecca Fahrig  
Radiology, Stanford University, Stanford/CA/UNITED STATES OF AMERICA

During the completion of my Bachelor’s degree in Physics at the University of Toronto, I became interested in Medical Physics, which led me to pursue a Master’s in Medical Biophysics from the University of Toronto. I completed my PhD in Medical Biophysics from the University of Western Ontario, where I focused on novel x-ray imaging techniques. I was awarded a Post-Doctoral Fellowship by the Medical Research Council of Canada, which I completed at Stanford University. Following my fellowship, I joined the faculty at Stanford School of Medicine, where I am currently a Professor (Research) of Radiology. I have had the honor of receiving the Young Investigator’s Award from the American Association of Physicists in Medicine, and the Greenfield Award for Best Paper published in Medical Physics. I have published over 100 peer reviewed articles and I am currently the PI on two NIH funded grants. At each stage of my career I have been fortunate to have mentors who have provided sage advice and guidance. I look forward to an exciting World Congress and the opportunity to share my experience in the Gender, Science, and Technology Track.
SP011.5 - Early exposure to science leads to fulfilling career in medical physics
Author(s): Renee X. Larouche
Radio-oncologie, CHUM - Hôpital Notre-Dame, Montreal/Canada

I have a happy and fulfilling career working in the field of clinical medical physics for almost 13 years. Although I love my work, finding the perfect balance between work, family life, and volunteering is not an easy task to accomplish. After working in two community radiation oncology clinics, one in Canada and the other in the USA, I finally settled in Montreal. I am now currently employed at the Centre hospitalier de l’Université de Montréal (CHUM- Notre-Dame hospital) in the department of radiation oncology. My general interests are in safety and risk management as well as the implementation of more robust processes in the clinic. Since 2012, I am the Deputy Chief Examiner for the Canadian College of Physicists in Medicine (CCPM). This opportunity allows me to meet a number of young medical physicists from all across Canada.

My life experience in the world of sciences has been very positive. I have received encouragement, worked in nurturing conditions and have had great role models. I was exposed to physics at a very young age when a neighbor who was a physicist recognized my interest in science and nurtured it. In high school, I enrolled in a special science program. This constructive early exposure to science kept me motivated.

We were only three female students majoring in undergraduate physics. The gender issue had never been so obvious. The small number of women did not impact my sense of belonging. Although I felt lonely at times, I wanted to be a physicist just as much as anyone else in that classroom. Fortunately, I met a group of young women enrolled in science or engineering programs and we found ourselves together. The gender issue had never been so obvious. The small number of women did not impact my sense of belonging. Although I felt lonely at times, I wanted to be a physicist just as much as anyone else in that classroom. Fortunately, I met a group of young women enrolled in science or engineering programs and we found ourselves together. This was a great time in my life: in fact, a friend I made through WISE women enrolled in science or engineering programs and we found ourselves together. This was a great time in my life: in fact, a friend I made through WISE.

As a graduate student in medical physics, I realized that confidence plays a major role when expressing your ideas. Indeed, more importance was given to oral expression during exams than when I was an undergraduate student: I had never experienced the somewhat daunting situation of being questioned by a panel of examiners orally before. I will always remember the stress and fear associated with these exams, but I found that being well prepared and organized was key and is still the solution in my case. I keep this in mind when preparing oral exams for the CCPM.

Fear is often a hurdle for someone to attain his or her potential: fear of not succeeding, fear of ridicule or fear of rejection. The truth is that you are letting yourself down when deciding not to try. Getting out there, pushing yourself is how you are able to develop and, looking back, be proud of what you have accomplished.

SP013 - MRI: Methods

SP013.1 - Numerical Simpson’s Rule for Real Time and Accurate T2* maps generation Using 3D Quantitative GRE
Author(s): Chemseddine Fatnassi, Rachid Boucenna, Habib Zaidi
1Radio-oncology Department, Hirslanden, Lausanne/SWITZERLAND, 2Department Of Nuclear Medicine And Molecular Imaging, Geneva University Hospital, Geneva/SWITZERLAND

Introduction: Quantitative T2* maps can be generated using different approaches, the golden standard being the nonlinear least square (NLLS) exponential signal decay fitting technique. It can also be generated using a logarithmic linear fit (LLF). However, the above mentioned methods based on curve fitting are time consuming and their use in real time challenging. NumART2* approach introduced by Hagberg et al. (2002) computes in real time the T2* but remains echo spacing and signal noise dependent. In this work, we propose an alternative approach relying on Simpson’s rule integration that generates in real time accurate T2* maps even in the presence of large echo spacing and high noise value.

Materials and Methods: We propose a method based on Simpson’s rule for integrating the temporal signal decay. Instead of a linear approximation (e.g. NumART2*), Simpson’s rule combines trapezoidal and midpoint rules to better interpolate the signal decay between echoes. To test our hypothesis, we used simulated brain MRI data (MNI, Canada) and 20 in vivo scans performed on a 3T Magnetom Trio (Siemens Healthcare, Erlangen, Germany) using the following parameters: Echoes/GRE/α/TR/TE1/ΔTE/size=32/Bipolar/8°/47/1.23/1.23ms/136×136×112. An offline generation of T2* maps was realized using LLf, NLLS (expo) and NumART2*. The maps were evaluated and compared in terms of signal echo spacing and image noise level.

Results and Discussion: In the presence of small echo spacing (ΔTE/T2*<0.2), the T2* maps were well generated by all methods, with a slight overestimation when using NumART2*. When ΔTE increases (ΔTE/T2*>0.2), NumART2* tends to overestimate the T2* values, although accuracy is well maintained by the other methods. These results can be explained by the quadratic interpolation of signal decay between the echoes that Simpson’s rule uses to approximate the area under the signal decay rather than a linear approximation that NumART2* uses. For low noise levels (<15%), all methods provide highly accurate results. NumART2* starts to diverge when the noise level becomes significant (>15%), while Simpson’s rule, linear and NLLS fit remain insensitive to added noise. Simpson’s rule combines two approximations, namely the midpoint and trapezoidal rules, to compute the signal integral. This combination enables to approximate well the signal decay between two echo points using a smooth quadratic interpolation even in the presence of high noise level, and as such, provides accurate T2* maps.

Conclusion: We proposed an alternative T2* maps generation which relies on Simpson’s rule to approximate the geometric area under the signal decay. The method allows rapid whole brain mapping of T2* with a high accuracy even in the presence of large echo spacing and high noise level.
SP013.2 - Optimization of Pulse-Triggered fMRI Measurement Delay with Acoustic Stimulation

Author(s): Anita Król1, Zofia Drzaza2, Uwe Kloese1
1Medical Physics, A Carolinum Institute of Physics, University of Silesia, Katowice/POLAND, 2Diagnostic And Interventional Neuroradiology, University Hospital Tübingen, Tübingen/GERMANY

The purpose of the study was to examine whether improvement of activation maps of auditory cortex and brainstem nuclei is possible when the delay between the cardiac induced pulse signal and the measurements is optimized. Subsequently, the comparison of the height of brain activity obtained for different stimuli- classical and rock music. In five healthy, right- handed volunteers (the mean ages 25.4 ± 2.8 years old), musical stimuli were presented binaurally in a block design. Evaluation was performed using 'Matlab' and 'SPM-8new' software with statistical threshold p< 0.001 (auditory cortex, AC) and p< 0.01 (brainstem). Our results suggest that the manipulation of the trigger delay (TD) time changes the degree of activation in auditory cortex and brainstem nuclei. Detection of auditory cortex was in 16% (TD=0), 30% (TD=200), 8% (TD=400) and 9% (TD=800) higher than without cardiac gating examinations, and correspond to the 41 and 22 Brodmann areas. The 3-selected slices volume included the medial geniculate bodies (MGB), lateral lemniscus nuclei (NLL), superior olivary complex (SOC) and cochlear nuclei (CN). The height of activation depends on duration of trigger delay. Therefore, using various TD time proves that it is possible to increase ability to detect activation in subcortical auditory structures - another method to reduce image signal variability, which was caused by brainstem motion. Examinations with rock type of music bring better than classical.

SP013.3 - Improvement of Pseudo Multispectral Classification of Brain MR Images

Author(s): Chemseddine Fatnassi1, Rachid Boucenna1, Habib Zaidi2
1Radio- oncology Department, Hirslanden, Lausanne/SWITZERLAND, 2Department Of Nuclear Medicine And Molecular Imaging, Geneva University Hospital, Geneva/SWITZERLAND

Introduction: Several advanced applications using morphological MRI frequently require segmentation of the imaged volumes. The accurate interpretation of information pertaining to investigation of brain alterations relies on accurate and reproducible brain tissue classification. Different approaches based on thresholding, cluster analysis, a priori information about anatomy and Bayesian classification have been proposed. However, many of them fail when classifying specific regions with low contrast between tissues. In this work, we introduce an enhanced method to classify brain tissue by combining a pseudo-multispectral color transformation (PMC) and improved K-mean clustering. The proposed approach is compared with FSL classification (FMRIB, Oxford, UK).

Materials and Methods: Gray and binary color spaces are commonly used by image processing methods. However, the contrast between brain tissues in some regions is very low e.g. cerebellum(WM and GM interfaces). Consequently, methods fail and wrong classifications might occur. To overcome this problem, the first step consists, after skull stripping, in transforming the T1-MPRAGE data to multispectral data containing 3 different images CIE-XYZ. To better separate neighboring values in WM, GM interfaces, normalized 3-channel data values are weighted by root square function (RSF). RSF minimizes low contrast region brain tissue overlapping. In the second step, an enhanced iterative and non-deterministic K-mean clustering is applied for image classification. The number of K-clusters is initially set to be maximal; the algorithm repeats classification with decreasing K until convergence. Subsequently, gap criterion, used to evaluate the optimal number of clusters, is calculated. Optimal K-cluster is then estimated. In addition, GM, WM and CSF centroid distribution templates are estimated beforehand using more than 70 human and a couple of simulated data. Based on these parameters, brain tissue classes computed earlier are corrected and reassigned to the new optimal classes. To evaluate our approach, we used 4 numerical brain atlas templates where GM, WM and CSF volumes are known beforehand (ground truth). In addition, 10 clinical MRI studies scanned on a 3.0T Skya (Siemens Healthcare, Germany) using T1-MPRAGE sequence with the following parameters: flip/TE/TR/TI=100/4/9.7/20ms. These data sets were classified using PMC and then compared with FSL classification.

Results and Discussion: The numerical brain tissues are classified using the enhanced PMC algorithm with a high accuracy (90% for WM, 101% for GM and 108% for CSF) against FAST-FSL (85% for WM, 119% for GM and 86% for CSF). Silhouette plot indicates that PMC better separates clusters compared to FAST-FSL classification even in presence of low CNR and partial volume effect. The clinical studies show that the proposed approach is faster and more accurate, especially in region with low CNR e.g. cerebellum artery vitae where the WM and GM are better delineated.

Conclusion: It can be concluded that enhanced PMC classification provides a fast and accurate brain tissue classification. This approach overcomes the low CNR and partial volume effect present in some brain regions, e.g. cerebellum artery vitae and near the temporal lobe region and seems to be promising for clinical and research applications.

SP013.4 - Image reconstruction of RF encoded MRI signals in an inhomogeneous B0 field

Author(s): Samea Saleajeghe1, Paul Babyn2, Jonathan C. Sharp3, Gordon E. Sarty1
1Biomedical Engineering, University of Saskatchewan, Saskatoon/CANADA, 2University of Saskatchewan, Saskatoon/CANADA, 3University of Alberta, Edmonton/CANADA

Introduction: Conventional Magnetic Resonance Imaging (MRI) use a uniform main magnetic field (B0) to polarize the sample being imaged. Non-homogeneity in the B0 field leads to image distortion. In practice it is impossible to have a perfectly homogeneous B0 field so shim coils are used to remove the inhomogeneity of the field. However, shim coils and other B0 homogeneity requirements result in expensive and heavy MRIs. To produce truly portable MRI equipment, the requirements for homogeneity of the B0 field could be removed. When used with TRansmit Array Spatial Encoding (TRASE) [1] to encode information instead of using traditional B0 gradient coils an MRI with an inhomogeneous field could be portable [2]. The TRASE method encodes spatial information through the use of spatially varying B1 transmit phase fields. The feasibility of the reconstruction of TRASE signals under B0inhomogeneity from a mathematical perspective was investigated.

Method: TRASE signals were simulated for a discrete Shepp and Logan mathematical phantom inside a TRASE RF coil set, composed of a combination of circular Maxwell and Helmholtz coils, in an inhomogeneous B0 field. The field assumed was \( B_0(x,y) = A x^2 + B y^2 + C \) where \( A = 0.1, B = 0.2 \) and \( C=0.08 \). The simulated TRASE MRI signals were reconstructed using a regularized least squares reconstruction method. The signal from the phantom \( p \) can be written in matrix form, with appropriate re-indexing of the collected signal data points, as \( S = [T] p \). The image may then be reconstructed using constrained least squares technique. Here a regularized least squares reconstruction was done by adding Tikhonov regularization as \( R = \text{argmin} \{ \langle [T] R - S \rangle^2 + \mu \| R \|^2 \} \), where \( \mu \) is a regularization parameter, \( \| \) is the identity matrix and \( R \) gives the approximate solution for \( p \).

**SP014.2 - Improved Semi-automated 3D Kinematic Measurement of Total Knee Arthroplasty Using X-ray Fluoroscopic Images**

**Author(s):** Takaharu Yamazaki¹, Ryogo Kamei², Tetsuya Tomita³, Yoshinobu Sato⁴, Hideki Yoshikawa⁵, Kazuomi Sugamoto³

¹The Center For Advanced Medical Engineering And Informatics, Osaka University, Osaka/JAPAN, ²Ritsumeikan University, Shiga/JAPAN, ³Orthopaedic Biomaterial Science, Osaka University Graduate School of Medicine, Osaka/JAPAN, ⁴Nara Institute of Science and Technology, Nara/JAPAN, ⁵Orthopaedics, Osaka University Graduate School of Medicine, Osaka/JAPAN

Accurate measurement of 3D dynamic kinematics of total knee arthroplasty (TKA) is very important for evaluating the outcome of surgical procedures and for improving the implants design and clinical outcome. In order to achieve 3D kinematic analysis of TKA, 2D/3D registration techniques, which use X-ray fluoroscopic images and computer aided design (CAD) model of the knee implants, have been applied to clinical cases. However, in previous study, these techniques have needed time-consuming and labor-intensive manual operations in some process, and particularly the process of the manual initial guess poses of the CAD model for each X-ray image was problem for practical clinical applications. In this study, we propose an improved method for semi-automated 3D kinematic measurement of TKA using X-ray fluoroscopic images. The proposed initial pose estimation method of the model is based on the use of a transformation with feature points extracted from each X-ray image using speeded up robust features algorithm. In order to ensure the validity of the proposed method, in vivo experiment using X-ray fluoroscopic images of 4 TKA patients during knee motions was performed. As a result of experiment, 3D pose of the model for all X-ray images except for the first frame was automatically stably-estimated, and the success rate (X-ray frame number within error of 1mm / 1 degree relative to all X-ray frame number) for the femoral and tibial component were 83.7 % and 73.5 %, respectively. In addition, the success rate with the proposed method was higher than a conventional method. Consequently, the present method was thought to be very helpful for practical clinical applications.

**SP014.3 - The influence of screw length and stiffness on the tibial mechanical environment in ACL reconstruction**

**Author(s):** Jie Yao¹, Lizhen Wang¹, Yubo Fan²

¹School of Biological Science and Medical Engineering, Key Laboratory for Biomechanics and Mechanobiology of Ministry of Education, National Key Lab of Virtual Reality Technology, Beihang University, Beijing/CHINA, ²National Research Center for Rehabilitation Technical Aids, Beijing/CHINA

**Introduction & Objective**

Anterior cruciate ligament (ACL) reconstruction is the primary treatment for the ACL injury in orthopedics. However, the post-operative graft laxity has been frequently reported, which would cause knee instability and osteoarthritis in long-term [1]. The interference screw is the popular implant for the graft fixation. It may change the surrounding mechanical environment, induce the undesirable bone remodeling, and lower the graft fixation strength. Therefore, this study aimed to quantify the influence of the screw on the distribution of stress energy density (SED), which correlated with the bone remodeling.

---

**Fig. 1:** 128 *128pixel phantom and reconstructions. (a) Phantom. (b) Reconstructed image from a TRASE coil in a homogeneous B0 field. (c) Reconstructed image from a TRASE coil in an inhomogeneous B0 field.

**Results/Conclusion:** Fig. 1 shows regularized least squares inversion of simulated signals from a TRASE coil in an inhomogeneous B0 field. The result is comparable to the reconstruction from a signal generated in a homogeneous B0 field. This is the first step in showing that TRASE in an arbitrary B0 field is possible. The next steps include simulations via the Bloch equations to model the effect of inhomogeneities on the flip angles attained.

Methods
The finite element model of single-bundle ACL reconstruction was developed. The SED distributions in tibia under the compressive, valgus, and rotational loadings were applied. The influences of the screw length and stiffness on the post-operative SED were calculated.

Results & Discussion
The compressive loading played an predominant role among the three loadings. Under the compressive loading, the SED beneath the screw shaft was decreased, whereas the SED above the screw shaft was increased. Extremely high SED occurred near the screw head and tip.

Increasing the screw length would potentially promote the bone healing at the proximal part of the tunnel, yet aggravate the SED alteration at the distal part. Using a screw modulus approaching to the bone could reduce the undesirable SED alteration.

Conclusion
In ACL reconstruction, using a long screw with the modulus approaching to the bone could provide a beneficial mechanical environment for the post-operative rehabilitation.

SP014.4 - A new method for determining the effect of follower load on the range of motions in the lumbar spine
Author(s): Cheng-Fei Du1, Junchao Guo1, Yun-Peng Huang2, Yubo Fan3
1School of Biological Science and Medical Engineering, Bei-hang University, Beijing/CHINA, 2Department Of Orthopaedics, First Affiliated Hospital, FuZhou/CHINA, 3School of Biological Science and Medical Engineering, Key Laboratory for Biomechanics and Mechatronics of Ministry of Education, National Key Lab of Virtual Reality Technology, Beihang University, Beijing/CHINA

In this study, a new method of applying follower load in finite element (FE) model of lumbar spine was presented. The effect of follower load on the range of motions (ROM) in lumbar spine was also investigated. A three-dimensional nonlinear FE model of lumbar spine (L1-S1) has been developed and validated. Connector elements between each pair of endplates were created to apply follower load. The endpoints of each connector were close to the center of endplate. The follower load of 0N, 500N, 800N, 1200N were respectively applied to explore their influence on the motion response of lumbar spine to the moment of 7.5NM in three principle planes (extension, flexion, right bending, left bending, right torsion, left torsion). The results showed that the direction of follower load was almost along with the curvature of spine and induced very small segmental motion. The follower load made the ROM of lumbar spine slightly increase in extension, while produced the decrease in ROM in other five moments. This stiffening effect became more obvious with an increase in the follower load. The largest percent decrease in motion of lumbar spine due to pre-load was in left torsion (47%), and then right torsion(42%), right lateral bending (21%), left lateral bending(20%), flexion(11%).
Conclusions. Beta Enhancers show to be a complementary tool to improve the BNCT of very superficial tumors cases, without significant perturbation of the primary neutron beam used for the treatment.

SP015.2 - Nanoparticle Enhanced Radiation Therapies: Is There a Synergy with Chemotherapies?

**Author(s):** Linda J. Rogers¹, Herman Hau², Wojciech Chrzanskowski², David R. McKenzie³, Natalka Suchowerska¹

¹Radiation Oncology, Chris O’Brien Lifehouse, Sydney/AUSTRA-LIA, ²Faculty Of Pharmacy, University of Sydney, Sydney/AUSTRA-LIA, ³School Of Physics, University of Sydney, Sydney/AUSTRALIA

**Introduction**

Nanoparticles can enhance the radiation dose, but have exhibited cytotoxicity, which is highly dependent on the ability of nanoparticles to penetrate the cell membrane and accumulate within the cell. Both radiation enhancement and nanoparticle uptake is regulated by the nanoparticle surface characteristics, their size and chemical composition. The goal of this study is to identify the individual and combined synergistic toxicity of radiation therapy and chemotherapy with gold nanoparticles (GNPs). The existence of a synergy would enable the radiation dose and the systemic dose from chemotherapy drugs to be reduced, thereby reducing side effects. Local treatment efficacy, through the synergistic coupling with nanoparticles, would be enhanced.

**Method**

For the human colon adenocarcinoma (LoVo) cell line, the clonogenic survival response was determined for a 50 kVp beam produced by a Pantak and a 6 MV beam produced by a Varian Novalis linear accelerator, for the chemotherapy drug 5-fluorouracil (5-FU) and for GNPs of diameter 4 nm for a range of concentrations. The GNPs were manufactured using precipitation method and stabilised with PEG. The therapies were combined in pairs to identify individual synergies first, then all three (radiotherapy, nanoparticles and chemotherapy) were combined to establish cumulative effects.

**Results**

Radiation doses for both energy beams and concentrations of GNPs and 5-FU were chosen such that in combination a paired total loss in cell survival was predicted on the basis of no synergistic effects to be of approximately 50%. The doses used were 1 Gy (kV radiation), 2 Gy (MV radiation), 0.5 µg/mL 5-FU and 50 µg/mL GNPs. It was found that the cells are more sensitive in the kV beam than in the MV beam for the same dose (Figure 1A & 1B), the result of differences in LET. The 5-FU and GNPs at very low doses appear to cause an increase in clonogenic survival however this is not statistically significant.

**Conclusion**

The nanoparticle toxicity was measurable but small and was concentration dependent. The response to kV radiation produced a greater decrease in survival than MV radiation. The 5-FU response was determined and 50% survival was approximately 1 µg/mL. These results lay the groundwork for synergistic effects. In vivo studies will confirm the translation of our findings.

SP015.3 - Change in Hounsfield Units due to lung expansion as a predictor of LAD and heart displacement in patients undergoing deep inspiration breath hold for left sided breast cancer

**Author(s):** Petra Lonski¹, David Jolly¹, Boon Chua², Damien Philips³, Maria Portillo³, Steven David², Amanda Philips³, Tomas Kron¹

¹Physical Sciences, Peter MacCallum Cancer Center, Melbourne/AUSTRALIA, ²Department Of Radiation Oncology, Peter MacCallum Cancer Center, Melbourne/AUSTRALIA, ³Radiation Therapy Services, Peter MacCallum Cancer Center, Melbourne/AUSTRALIA

**Aim:** Deep inspiration breath hold (DIBH) is a cardiac sparing technique for patients with left sided breast cancer undergoing external beam radiotherapy. Little work has been published on patient-specific quality assurance for DIBH. This study aims to assess the relationship between change in lung Hounsfield Units (HU) that occurs between a free breathing (FB) CT scan and deep inspiration breath hold (DIBH) scan and the displacement of the heart and left anterior descending (LAD) coronary artery from the radiation target volume.

**Methods:** Ten consecutive left sided breast cancer patients underwent a FB and a DIBH CT scan. A single clinician contoured the heart and LAD for all patients. The mean lung HU were sampled over a 2 cm (length) area spanning across the lung on the coronal plane above the diaphragm. For assessment of heart and LAD displacement, a line was drawn on the axial slice using the CT software between the medial and left lateral ball bearings to define a region of interest (reference line), which typically would correspond to a high dose region. The distance of the anterior aspect of the LAD, as well as the amount of heart present from this line was measured on both scans.

**Results:** The heart and LAD displacement measured from the reference line as a function of the relative change in HU is shown in Figure 1 and 2, respectively. Displacement was found to increase with relative change in HU for the left lung. There was no significant correlation with the right lung.
Materials & Methods — The cation-exchange resin, Amberlite IR-120 (Sigma Aldrich, USA) which is commercially available in large beads (620-830 μm), was crushed and sieved into size of 20-40 μm and labelled with 1 g of 152SmCl3 salt prior to neutron activation. Therapeutic activity of 3 GBq 153Sm was aimed based on the standard activity used by the 90Y SIR-Spheres. The samples were irradiated in 1.494 x 1012 n.cm².s⁻¹ neutron flux for 6 h. Characterization of the microparticles, gamma spectroscopy, and in-vitro radiolabelling studies were carried out and compared to a commercially available resin readily made in 20-40 μm, Fractogel EMD SO3⁻ (S) (Merck, Germany).

Results — Fourier Transform Infrared (FTIR) spectroscopy of Sm-Amberlite microparticles showed unaffected functional groups within the resin, following size reduction of the beads. However, the microparticles were irregular in shape as shown by the electron microscope. The radioactivity achieved after 6 h of neutron activation was 3.104 ± 0.029 GBq. The specific activity per microparticle for 153Sm-Amberlite and 153Sm-Fractogel were 55 Bq and 49 Bq, respectively. Gamma spectroscopy data showed that no radioactive impurities were detected in 153Sm-Amberlite samples but there was a detectable amount of 24Na in the 153Sm-Fractogel samples. Furthermore, Energy Dispersive X-ray (EDX) spectroscopy of Sm-Fractogel showed presence of chlorine impurity but no significant impurities were observed in 153Sm-Amberlite samples. Radiolabelling efficiency of 153Sm-Amberlite tested in distilled water and blood plasma were excellent (99.9 and 96.9%, respectively) whilst 153Sm-Fractogel showed lower labelling efficiency (82.3 and 92.9%, respectively) over a test period of 48 h.

Conclusion — Despite the irregular shape due to mechanical grinding of the resin, 153Sm-Amberlite formulation showed excellent radiolabelling efficiency and no impurities were detected during the labeling and neutron activation processes. In comparison, the presence of chlorine and 24Na in Sm-Fractogel formulation as well as its lower radiolabelling efficiency make it less suitable to be used for radioembolization of the liver tumour.

Conclusion — 153Sm-Amberlite microparticles presented suitable characteristics for liver radioembolization as an alternative to 90Y. It has advantage over the 90Y for being able to do post-procedure imaging to estimate treatment efficacy. Dosimetric study needs to be carried out to estimate radiation dose contributed by the gamma radiations from the 153Sm. Further animal studies are also needed to verify its in-vivo distribution, and biochemical stability.
models for EBRT treatment dose calculations obsolete, in most clinical situations. For pregnant patients however, the abdominal anatomy is routinely excluded or shielded, during the acquisition of the treatment planning CT, and therefore cannot be included in out-of-field dose calculations.

This study therefore aimed to take existing anatomical models of pregnant women, currently used for radiation protection and nuclear medicine dose calculations, and adapt them for use in the calculation of fetal dose from external beam radiotherapy (EBRT).

The models investigated were ‘KATJA’, which was provided as an MCNPX geometry file, and “RPI-P6”, which was provided in a simple, voxelized binary format. In-house code was developed, to convert both models into an ‘egsphant’ format, suitable for use with the BEAMnrc and DOSXYZnrc Monte Carlo codes. The geometries and densities of the resulting phantoms were evaluated and found to accurately represent the source data.

As an example of the use of the phantoms, the delivery of a cranial EBRT treatment was simulated using the BEAMnrc and DOSXYZnrc Monte Carlo codes and the likely out-of-field doses to the fetus in each model was calculated. All sources of out-of-field dose (radiation leakage from the linac head, scatter of the primary beam from the linac head and the intervening air, and scatter of the primary beam within the patient) were included in the simulation.

The results of these calculations showed good agreement (within one standard deviation) between the doses calculated in KATJA and PRI-P6, despite substantial anatomical differences between the two models. For a 36 Gy prescription dose to a 233.2 cm³ target in the right brain, the mean doses calculated in a region of interest covering the entire uterus were 1.0 +/- 0.6 mSv for KATJA and 1.3 +/- 0.9 mSv for PRI-P6.

This work is expected to lead to more comprehensive studies of EBRT treatment plan design and its effects on fetal dose in the future. The novel codes developed for this study may also be used to produce EBRT Monte Carlo simulation files from other radiation safety models, including pediatric patients of various ages.

---

**SP016.1 - 18F-NaF PET/CT-directed dose escalation in stereotactic body radiotherapy for spine oligometastases from prostate cancer**

**Authors:** Lili Wu1, Sandi A. Kwee2, Mei Li1, Xin Peng1, Liangxi Xie1, Zhixiong Lin1, Hui Wang3, Yu Kuang3

1Radiation Oncology, Cancer Hospital of Shantou University Medical College, Shantou/CHINA, 2Department Of Medical Physics, University of Hawaii, Honolulu/HI/UNITED STATES OF AMERICA, 3Department Of Medical Physics, University of Nevada Las Vegas, Las Vegas/NV/UNITED STATES OF AMERICA

**Purpose:** To investigate the technical feasibility of SBRT dose painting using 18F-NaF positron emission tomography (PET) scans guidance in patients with spine oligometastases from prostate cancer.

**Materials/Methods:** Six patients with 15 spine oligometastatic lesions from prostate cancer who had 18F-fluorine PET/CT scan prior to treatment were retrospectively included. GTVreg was delineated according to the regular tumor boundary shown on PET and/or CT images; and GTVMATV was contoured based on a net metabolically active tumor volume (MATV) defined by 60% of the SUVmax values on 18F-NaF PET images. The PTVs (PTVreg and PTVMATV) were defined as respective GTVs (plus involved entire vertebral body for PTVreg) with a 3-mm isotropic expansion margin. Three 1-fraction SBRT plans using VMAT technique along with 10 MV flattened filter free (FFF) beams (Plan24Gy, Plan24-27Gy, and Plan24-30Gy) were generated for each patient. All plans included a dose of 24 Gy prescribed to PTVMATV. The Plan24-27Gy and Plan24-30Gy also included a simultaneous boost dose of 27 Gy or 30 Gy prescribed to the PTVMATV, respectively. The feasibility of 18F-NaF PET-guided SBRT dose escalation was evaluated by its ability to achieve 100% of the prescription dose to cover at least 90% of the PTV volume while adhering to organs-at-risk (OARs) dose constraints.

**Results:** In all 33 SBRT plans generated, the planning objectives and dose constraints were met without exception. Plan24-27Gy and Plan24-30Gy had a significantly higher dose in PTVMATV than Plan24Gy (p < 0.05), respectively, while maintaining a similar OARs sparing profile.

**Conclusion:** Using VMAT with FFF beams to incorporate a simultaneous 18F-NaF PET-guided radiation boost dose up to 30 Gy into a SBRT plan is technically feasible without violating normal tissue tolerances. The relationship between local control and normal tissue toxicity during 18F-NaF PET-guided dose escalation in SBRT should be validated in clinical trials.

**SP016.2 - Evaluation of a lung tumor autocontouring algorithm for intrafractional tumor tracking using 0.5T linac-MR: phantom and in-vivo study**

**Authors:** Jihyun Yun, Eugene Yip, Zsolt Gabos, Keith Wachowicz, Satyapal Rathee, B Gino Fallone

Medical Physics, Cross Cancer Institute, Edmonton/CANADA

We developed an autocontouring algorithm for intrafractional lung-tumor tracking using linac-MR, and evaluate its performance with phantom and in-vivo MR images.

A pulse-coupled neural network is the main component of the algorithm responsible for tumor contrast improvement from its surrounding anatomy (normal lung, blood vessels). Prior to treatment, an expert user needs to contour the tumor and its maximum anticipated range of motion in pretreatment MR images. During
treatment, however, the algorithm processes each intrafractional MR image and automatically generates a tumor contour without further user input. The algorithm is designed to produce a tumor contour that is the most similar to the expert’s one.

To evaluate the algorithm in our linac-MR environment (0.5T MRI), a motion phantom and four lung cancer patients were imaged with 3T MRI at ~4 frames per second, and the images were degraded to reflect the image quality characteristic of lung tumor MR images at 0.5T. During scanning (~3 minutes), the phantom was driven according to four different 1-D motion patterns (sine pattern with 4 cm amplitude, 4 seconds period + three lung tumor motion patterns), and the patients were in free breathing. Each of these pseudo-0.5T images was autocontoured using our algorithm. In each test image, the Dice’s coefficient (DCE) and Hausdorff distance (HD) between the expert’s manual contour (ROIstd) and the algorithm generated contour (ROIauto) were calculated to measure their similarity, and their centroid position difference (Δdcentroid) was calculated.

Our algorithm successfully contoured the shape of a moving tumor from pseudo-0.5T MR images. Example images are shown in Fig. 1, and the autocontouring accuracy is summarized in Table 1. From the in-vivo study, we achieved 87–92% of contouring agreement and centroid tracking accuracy of 1.03–1.35 mm. These results demonstrate the feasibility of lung tumor autocontouring in our laboratory’s linac-MR environment.

SP016.3 - Multi-modal image registration for MR-guided radiotherapy workflow based on detection of features in a customized stereotactic body frame

Author(s): Paul Mercea1, Asja Pfaffenberger1, Markus Stoll1, Gernot Echner1, Armin Runz2, Regula Gnirs3, Florian Sterzing3, Tilmann Bostel4, Rolf Bendl4
1 Division Of Medical Physics In Radiation Oncology, German Cancer Research Center (DKFZ), Heidelberg/GERMANY, 2 Division Of Radiology, German Cancer Research Center (DKFZ), Heidelberg/GERMANY, 3 Department Of Radiation Oncology, University Hospital Heidelberg, Heidelberg/GERMANY, 4 Faculty Of Medical Informatics, Heilbronn University, Heilbronn/GERMANY

Introduction
Shuttle-based MR-guided radiation therapy with separate MR imaging and treatment devices requires both reproducible patient immobilization and robust multi-modal image registration. In the MR-guidance study [1] currently conducted at our institution a customized stereotactic body frame (CSBF) was developed to facilitate image registration. The aim of this work is to develop an algorithm for fast detection of features in the CSBF in order to support image registration for assessment of patient setup alteration.

Methods
The CSBF is equipped with a long (600mm) and a short (80mm) hose (inner diameter 2mm) filled with contrast agent. The former is bent in its middle at an angle of 28.07° surrounding the latter which is centered horizontally (see Fig. 1). Image data of one patient from the MR-guidance study cohort has been selected for evaluation. Besides the treatment planning CT, Cone-Beam CTs (CBCTs) and their corresponding T2 weighted MR images (MRIs) from 16 fractions were used. To identify lines representing the hoses in the images, a probabilistic Hough transform on thresholded gradient image slices is performed in posterior-anterior direction. Detected line pairs oriented towards each other most akin to a notional isosceles triangle formed by a straight line representing the short hose and two lines representing the tapering ends of the long hose are further analyzed. The image data is traversed along the triangle’s edges in search of local intensity maxima. Principle component analysis of the detected maximum intensity distribution enables refinement of the detected lines. Eventually, line intersections are re-calculated and used for landmark-based rigid registration.

Results
Evaluation of the algorithm was performed by registration of the detected points from each MRI and CBCT with interactively placed reference points in the planning CT. For the 16 MRIs the mean root mean square registration error (RMSRE) was 0.78mm and for the 16 CBCTs 0.97mm. Additionally, each MRI was matched to its corresponding fraction CBCT resulting in a mean RMSRE of 0.65mm. Registration results were also assessed qualitatively by visual inspection (see Fig. 1).

Conclusions
An algorithm for multi-modal detection of characteristic features in a CSBF was developed. Accurate results and robust performance on 32 image data sets were achieved. The benefits from incorporating this algorithm, as a preprocessing step, for patient position correction will be evaluated in future research.

SP016.4 - A phantom study of impact of probe metal artifact in planning dose for ultrasound-guided radiotherapy

Author(s): Lin Su1, Sook Kien Ng1, Yin Zhang2, Iulian Iordachita2, John Wong1, H T. Sen3, Peter Kazanzides3, Muyinatu A. Lediju Bell2, Kai Ding1
1 Department Of Radiation Oncology, Johns Hopkins University, Baltimore/UNITED STATES OF AMERICA, 2 Department Of Mechanical Engineering, Johns Hopkins University, Baltimore/MD/UNITED STATES OF AMERICA, 3 Department Of Computer Science, Johns Hopkins University, Baltimore/MD/UNITED STATES OF AMERICA

Image guided radiotherapy (IGRT) is gaining popularity in radiation oncology. Among different IGRT imaging modalities, ultrasound (US) is portable, affordable, and non-ionizing. To monitor the abdominal organ motion during IGRT, we previously developed a probe holder to reproduce the simulation probe position during treatment. However, the metallic parts inside the probe caused artifacts in the CT images (see Fig. 1). This work quantifies the influence of metal artifacts on the treatment plan.

A CIRS Triple Modality 3D Abdominal Phantom (model 057A) including kidneys, lung, and liver, with six tumors inside the liver was scanned using Phillips Brilliance Big Bore CT both with and without the probe in place. A passive arm was used to hold the probe with minimum pressure applied to avoid any phantom deformation. The CT scan without the probe was used for treatment planning in Pinnacle 9.8. Six tumors with distance 60–127 mm to the probe and organs at risk were contoured. Individual plan was made for each tumor. All tumors were prescribed to receive 4000 cGy dose in five fractions. Two VMAT partial arcs avoiding the US probe were
Objectives: This software tool was built to handle reference CT (rCT) and MR (rMR) images from treatment simulation as well as guidance CBCT and MR (gMR) images from daily image guidance. Key design goals include: (i) support various data formats such as DICOM CT, DICOM MR, DICOM spatial registration objects; (ii) provide communication and data flow between different imaging, treatment and storage devices; (iii) perform accurate and robust image registration; (iv) provide a user-friendly graphical interface for users to manipulate data and assess registration quality; and, (v) output couch coordinate shift information to correct patient position for treatment.

Methods: We designed the software to import reference CT and MR images as well as guidance CBCT and MR images from the Mosaic Data Director (MDD), accurately register the guidance MR image to the reference MR, and export couch correction information to the Varian external interface to drive the couch to the correct position. Furthermore, we have developed storage capability to save all patient data, images, and registrations as a DICOM secondary capture, which allows us to re-examine the case and study the MR-guidance performance over time.

Results: All image data from the simulated workflow were successfully loaded into our software tool. Registration of the reference MR to the guidance MR was successful with resulting mean squared errors (MSE) for the four phantom shifts of 0.23 mm, 0.40 mm, 0.11 mm, and 0.10 mm. Registration of the corresponding CT images was also successful with resulting MSE of 0.35 mm, 0.21 mm, 0.33 mm, and 0.26 mm. Couch corrections were generated based on the registration information and exported. Finally, each test case was saved as a DICOM file and stored within the database.

Conclusions: In this study, we demonstrated the successful implementation of a comprehensive image-guidance tool for the MRgRT system in the 3D Slicer platform. We plan to use this tool to study the MRgRT system’s performance in guiding patient positioning based on soft tissue contrast and develop novel applications to enhance the clinical value of MR-guidance in radiation therapy.

**SP016.5 - Software development for image guidance on the magnetic resonance-guided radiation therapy (MRgRTTM) system**

**Author(s):** Wenya Xia¹, Stephen L. Breen², An Wang², David Jaffray²

¹Radiation Physics, Princess Margaret Hospital, Toronto/Canada.
²Radiation Medicine, Princess Margaret Hospital, Toronto/ON/Canada.

**Background:** The magnetic resonance-guided radiation therapy (MRgRT™) system utilizes a moveable MRI system to provide image-guidance in a linear accelerator (Linac) vault. By exploiting the superior soft tissue contrast available with MR-guidance, our goal is to provide more accurate patient positioning based on internal soft tissue. To implement cone beam CT (CBCT) and MR guidance effectively, we developed a novel software tool using the 3D Slicer platform.

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP017.1 - Dosimetric Effect of Beam Angle on the Unflattened and Flattened Photon Beams: A Monte Carlo study

Author(s): James Chow1, A Owrangi2

1Princess Margaret Cancer Center, Toronto/Canada, 2University of Michigan Health System, Ann Arbor/United States of America

This study compared the variations of depth and surface dose on beam angle between the unflattened and flattened photon beams. Monte Carlo simulation based on the EGSnrc code was used in dose calculation. Phase-space files of the 6 MV photon beams (field size = 10 X 10 cm²) were generated with and without the flattening filter based on a Varian TrueBeam linear accelerator. Depth and surface doses were calculated in a water phantom with angles of the photon beams turning from 0° to 90°. Our results showed that compared to the flattened photon beam, the unflattened beam had a higher dose in the build-up region but lower dose beyond the depth of maximum dose. With the Monte Carlo beams cross-calibrated to the machine monitor unit in simulations, dose ratios of the unflattened to flattened beams were in the range of 1.6 – 2.6 as shown in Figure 1 with beam angles varying from 0° to 90° in water. In addition, higher surface doses of about 2.5 were found with beam angles equal to 0° and 15°. However, surface dose deviation between the unflattened and flattened beam became smaller with an increase of beam angle. Using the photon fluence incorporated to the monitor unit, variations of depth and surface dose on the beam angle were investigated and compared. For the unflattened and flattened photon beams, the surface dose and range of depth dose ratios (unflattened to flattened beam) decreased with an increase of beam angle.

Fig. 1: Relationship between the dose ratio (unflattened to flattened photon beams) and depth.
Results:
The Monte Carlo calculated dose rate constant $\Lambda$ of the $^{125}$I in water was found to be 0.992 $\pm$ 0.025 cGyU$^{-1}$ h$^{-1}$. Radial dose functions of the new source model based on point and line source approximations were calculated at distance ranging from 0.1 to 7 cm. Moreover, $g_L(r)$ was measured in Plexiglas phantom material using TLD chips. In addition, the 2D anisotropy function, $F(r,\theta)$, were calculated and measured in both Plexiglas and water phantom.

Conclusions:
The results of these investigations show an agreement of about ±7% between the measured and simulated data in Plexiglas. The statistical uncertainty of MC within ±5% relative to the previously published data for different brachytherapy sources. Based on the results, the Monte Carlo simulated dosimetric parameters of the new $^{125}$I source in water are recommended for their clinical applications.

SP017.3 - Assessment of RayStation treatment planning algorithm to calculate dose in the presence of lung tissue

Author(s): Manuel Rodriguez, Mohammad Rezaee, Steve Bartolac, Jean-Pierre Bissonnette

Department Of Radiation Oncology, University of Toronto, Toronto/CANADA

Purpose: To investigate the accuracy of RayStation treatment planning algorithm to calculate absorbed dose when the photon beam is disturbed by attenuation or lateral scatter of lung material.

Materials:
A farmer type ion chamber was placed in the center of 30x30x20 cm$^3$ water phantom with a 5 cm lung material slab at 3 cm form the chamber when the beam was perpendicular to the lung slab and at 1 cm from the chamber when the beam was parallel to the lung slab. A SSD=100cm PDD curve was also measured placing a Gafchromic EBT2 film in the interface of the solidWater-lungSlab with the lung slab parallel to the beam and starting at 10 cm depth. Measurements were taken for 6 and 18 MV photon beams and for 10x10, 5x5 and 3x3 cm$^2$ field sizes. The ratio of the dose with and without the lung slab is reported.

Results:
The ratio of the measured dose with and without the lung slab (Dlung/Dsw) is within 1% of that ratio calculated by RayStation algorithm for all energies and field sized used when the beams are parallel and perpendicular to the lung slab (table 1). The PDD curves measured with gafchromic film with and without the presence of lung slab agree with those calculated by RayStation algorithm within the uncertainty of the measurements (figure 1), which is within 3%.
Conclusion:

RayStation dose calculation algorithm takes into account inhomogeneity corrections. It models attenuation of the beam and lateral scatter within 1% of points measured with ion chambers. PDD curves in the presence of lung material also agree with gafchromic film measurements within the uncertainty of the measurements. Therefore, RayStation has an acceptable algorithm to correct dose from photon beams perturbed by lung tissue.

SP017.4 - Improving the efficiency of charged particle transport in magnetic fields in EGSnrc

**Author(s):** Victor Malkov, David W.O. Rogers

Department Of Physics, Carleton University, Ottawa/CANADA

Image Guided Radiation Therapy (IGRT) technologies aim to improve the accuracy of the delivery of radiation with the hopes of decreasing damage to healthy tissues and sensitive organs. Synergistic MRI-Radiation therapy machines are a developing technology that can provide improved tumour tracking during treatment to help accommodate for patient motion or unaccounted for bodily changes over the full course of treatment. Porting the advantages of MRI technology into IGRT comes with the cost of introducing a magnetic field around the patient while a radiation beam is present. This magnetic field (MF) causes curvature in the charged particle trajectory, and can lead to significant variations in dose distributions, particularly at tissue-air interfaces, and lead to changes in the dose response of detectors. Our aim is to evaluate our implementation of the influence of the MF in the EGSnrc Monte Carlo code system, and deliver a detailed study of the increased computational requirements of our code. Monte Carlo (MC) codes have become a staple in radiation treatment planning systems, and are extensively used in radiation dosimetry and Medical Physics research. The EGSnrc code, a popular general purpose MC package used in Medical Physics, previously supported charged particle transport in magnetic fields, but in the transition from EG4 this feature of the code went untested. Our implementation is based a framework similar to the one originally proposed by Bielajew, but have introduced a higher order integration algorithm for the condensed history mode and made use of the single scatter algorithm in the EGSnrc code. To properly handle region transitions, additional changes were made related to the boundary crossing algorithm. These alterations lead to a reduction in the total required computational time compared to the previous implementation since larger step sizes can be taken during the simulation. These improvements prove crucial since the original theory required strict step size reduction which can lead to two to 30 fold increases in computation time as compared with the 25% to 50% increases with the current algorithm. The presented results will highlight ion chamber calculations as a function of magnetic field strength and step size constraints to demonstrate the importance of proper selection of system parameters to obtain accurate solutions. These results will be of particular benefit for groups looking to make use of the EGSnrc code or another MC package for calculating dose distributions in the presence of magnetic field. The improved computational efficiency of the presented code reduces the need for large computational facilities, making it a valuable research tool for investigating the effects of magnetic fields on radiotherapy treatments.

SP017.5 - Accurate Monte Carlo dose calculations for permanent implant prostate brachytherapy: first results from a large scale retrospective study

**Author(s):** Nelson Miksys¹, Eric Vigneault², Luc Beaulieu³, Rowan Thomson⁴

¹Department Of Physics, Carleton University, Ottawa/CANADA, ²Université Laval Cancer Research Centre, Quebec City/CANADA, ³Department De Physique Et Centre De Recherche En Cancerologie, Universite Laval, Quebec City/CANADA

Recently, the joint AAPM-ESTRO-ABG-ABS TG-186 report endorsed Monte Carlo (MC) dose calculations for brachytherapy as they are more accurate than the traditional TG-43 water-based paradigm. MC dose calculations require accurate patient-specific computational models often derived from post-implant CT images. We have explored issues related to the accurate modelling of the patient geometry by investigating algorithms to mitigate seed artifacts in addition to comparing detailed schemes for mapping image CT numbers to tissue type and mass density in the MC models. Here, we present our advanced MC patient-specific modelling approaches and initial dosimetric results of the first large retrospective MC dose calculation study (of approximately 1000 patients).

The EGSnrc user-code BrachyDose is employed for MC dose calculations of clinical prostate brachytherapy. Seed artifacts are mitigated by applying a metallic artifact reduction (MAR) algorithm to post-implant CT images. Artifact- mitigated images are used to derive MC phantoms by applying one of several tissue assignment schemes (TAS) mapping voxel CT number to tissue composition and mass density. MC-calculated dose distributions and clinical dose metrics for the target and OARs (organs-at-risk) are compared to each other (between different MAR and TAS models) and to TG-43 water-based calculations.
Materials and methods

The bremsstrahlung dose component in electron beams arises from four main sources considered in our model: scattering dual-foils, collimator jaws, applicator’s scrapers and insert of cerrobend. We have neglected the bremsstrahlung generated in the patient. Our model consists in two main parts: in the first part, we calculate the angular energetic fluence distribution for every bremsstrahlung photon source, using an existing model based on a multi-scattering theorem. In the second part, we calculate the relative number of pixels irradiated by the primary electron beam in every bremsstrahlung photon source. All programmings were executed by Matlab. All detailed information about the geometry, material composition, and size of each component have been provided by the manufacturers. Most of the data on the electrons interactions with matter are based on ICRU-1984 data. Measurements of bremsstrahlung dose component were achieved with TLD-700 powder thermoluminescent dosimeters, from 0 cm to 70 cm from the beam central axis, at a depth of 10 cm in a water phantom for a Varian 2300C/D Linac, operated at 6,9,12 and 18MeV.

Results

We demonstrate that out-of-field bremsstrahlung dose is essentially produced by applicator’s scrapers, while the out-of-field bremsstrahlung dose generated in scattering dual-foils can be neglected. In-field bremsstrahlung dose comes essentially from scattering dual-foils, which represents 70%-80% of total in-field bremsstrahlung dose. Our modelling results show a very good agreement between calculated and measured values, in-field and out-of-field. The average difference between calculated and measured values is less than 10%, which represent a very small difference in absolute dose.

Conclusion/perspective

Our approach can be used to provide a good representation of bremsstrahlung dose distributions in all healthy tissues for any applicator size and type and for any electron beam energy used in high-energy electron beam therapy.
The current state-of-the-art in radiotherapy (RT) is precision fractionated irradiation of tumors, with intended sparing of the surrounding normal tissue. To achieve this, highly accurate methods to aim radiation beams with complex static or dynamic shapes have been developed. In addition, various forms of anatomical and functional imaging (e.g., CT, PET, MR) have been integrated with the irradiation technology to achieve accurate targeting and dose verification. This integration was achieved using complex treatment planning software. These innovations are largely responsible for improved cancer treatment outcomes in recent years, rather than an improved fundamental insight in radiation response of normal and cancer tissues.

To gain more fundamental insight, and also to allow investigating the combination of radiation and other cancer agents, recently much progress was made towards developing advanced small animal combined irradiation/imaging platforms. The recent availability of small animal image-guided precision radiotherapy devices (Fig 1) in a growing number of centers is currently revolutionizing preclinical research. Researchers now can perform SmART (Small Animal RadioTherapy) research with devices that combine precise irradiation with high-resolution imaging in one system; the concept of image guided RT (IGRT). The essential components of a SmART research platform are: precision animal positioning, precision irradiation with small photon beams, onboard CT imaging and onboard bioluminescent imaging, all in the same coordinate system. In addition, an accurate treatment planning software for small animals, SmART-Plan, was developed at our institute. We recently added inverse planning capabilities to SmART-Plan to improve workflow and standardization of preclinical studies.

Several preclinical trials have been initiated at our institute. As an example, we used precision image-guided irradiation of the upper right lung lobes of 76 C57BL/6 adult male mice, with doses of 0-20 Gy. We used image registration and image analysis in this longitudinal study to establish a dose response for radiation-induced lung fibrosis. It was found that the mice were more resistant for high doses of irradiation preclinical studies are reported. This is one of the first studies where accurate irradiation and image analysis are used on such a scale. Many other experiments are being performed or planned now.

The final aim is to identify those combined novel treatments that have the best chance of success for clinical translation. In this work, we will report on the progress of the research in this new field at our institute.

SP018.2 - Longitudinal MRI evaluation of whole brain radiotherapy on brain metastasis development and dormancy in a mouse model
Author(s): Donna H. Murrell, Niloufar Zarghami, Michael D. Jensen, Ann F. Chambers, Eugene Wong, Paula J. Foster
Medical Biophysics, Western University, London/ON/CANADA

A major challenge in breast cancer treatment is its ability to metastasize – commonly to liver, lung, bone, and brain – thereby complicating detection and therapy. When cancer cells arrive at distant sites, they may experience different fates: (1) death, (2) proliferation creating metastases, or (3) dormancy (remaining viable but non-proliferative).

This work uses high-resolution anatomical and iron-labelled cellular MRI techniques developed in the Foster lab (Heyn et al., Magn Reson Med, 2006) to monitor cancer cell fate in the brain during metastasis progression. We combine this with image-guided micro-irradiation techniques developed in the Wong lab (Jensen et al., Med Phys, 2013) to investigate the growth of brain metastatic breast cancer and concurrent responses of metastases and dormant cancer cells to whole brain radiotherapy (WBRT).

Two animal experiments were performed (n=24): (1) ‘Late’ WBRT delivered when MRI-detectable tumours had developed; this is similar to the case of clinical diagnosis, or (2) ‘Early’ WBRT given following initial cancer cell arrest in the brain, prior to tumour growth.

‘Late’ WBRT was able to halt tumour growth. At 11 days post-therapy, the average volume of a treated tumour was significantly smaller than untreated (p<0.01); however, the number of MRI-detectable tumours did not decrease and some tumours continued to grow.

‘Early’ WBRT was more effective than ‘late’ and was able to eradicate nearly all tumours [C]. The number of metastases and total tumour volume in treated brains were significantly less than untreated (p<0.05). There was a reduction in the number of MRI signal voids from solitary iron-labeled cancer cells) over time; however, there was no significant difference between groups at any time point. Signal voids from non-viable cells are cleared from the brain; therefore, residual signal voids observed here are potentially viable dormant cells. This suggests dormant cancer cells can persist and are potentially viable, even if WBRT is delivered very early and has eliminated the tumour burden. Further investigation of the dormant cell population is warranted as these may respond to future proliferation signals and contribute to cancer recurrence.
SP018.4 - Tissue characterization using dual energy cone beam CT imaging with a dedicated small animal radiotherapy platform  

**Author(s):** Patrick V. Granton¹, Guillaume Landry², Mathieu Gaudreault³, Frank Verhaegen⁴  
¹Physics, London Regional Cancer Program, London/ON/CANADA, ²Department Of Medical Physics, Ludwig-Maximilians-University, Munich/GERMANY, ³Département De Radio-oncologie, CSSS de Chicoutimi, Chicoutimi/CANADA, ⁴Radiotherapy, Maastro Clinic, Maastricht/NETHERLANDS  

**Purpose**  
There is a growing number of preclinical image-guided high-precision conformal irradiation devices tailored to small animal geometries. Typically, 225kVp is used as the treatment photon energy. A potential error in the dose prescription lies in the dose calculation phase where there is uncertainty in the tissue composition. Dual-energy CT (DECT) provides estimates of the effective atomic number (Z_{eff}) and relative electron density re when two CT images are acquired at different energies. As Z_{eff} describes tissue composition, DECT of small animals could yield 1) information on the adequacy of approximating mouse tissues by tabulated human compositions and 2) improved tissue assignment for Monte Carlo-based dose calculation algorithms. The goal of this work was to optimize the selection of kVp-pairs, and investigate a recent DECT algorithm for robustness, accuracy, and precision using a dedicated small animal irradiation platform.

**Materials**  
Two mouse-sized phantoms, one acting as DECT calibration and the other as DECT validation, were custom-made from inserts of the...
identified and delineated on CT data obtained from each one of the implanted tumours. Volume reconstruction was performed on each injection site (Figure 1c-e), in order to quantify Au NP diffusion. At t = 2h (n = 3), 1 day (n = 4) and 8 days (n = 8), the tumours were harvested and radioactivity-counted. An organ biodistribution study was also performed (liver, spleen, kidneys, lungs). In 8/11 animals, the total activity retention in the tumours was higher than 80% of the total activity in the animal (93.2% ± 7.7%). After 8 days, the % of total activity retained in the tumours, was (92.0% ± 12.1%). Liver activities higher than 20% of the total animal activity were found in 3 animals, indicating that, in some injection and tumour conditions (e.g. vascularization of the tumour, interstitial fluid pressure), a fraction of Au NPs is taken up by the vasculature and immune cell processes, ending up in the organs associated to the reticuloendothelial system (liver, spleen). In resume, 

103Pd:Pd@Au-PEG NPs were efficiently synthesized (rapidity, reaction yield, colloidal stability, NPs concentration, purification), injected in prostate cancer tumours, and efficiently visualised in CT. In the perspective of clinical applications, the liver and spleen Au NP uptake must be adequately controlled by using either a polymeric or a molecular cancer cell targeting strategy to secure the retention of NPs in tumours.

Gammex (RMI467) and CIRS (062MQA) electron density calibration phantoms, respectively. The phantoms were imaged using a preclinical irradiator (XRAD225Cx, PXI) for a series of kVp settings (40-100) in increments of 10 kV. The exposures were adjusted to yield air kerma equivalent imaging dose of 30 cGy for each kVp. Images were decomposed into Zeff and re for each kVp pair and compared against referenced values. The best energy pair was chosen on the basis of accuracy and noise for both Zeff and re. The experimental DECT imaging was compared against simulations using a CT software package (imaSim) with different amounts of image noise. DECT imaging of a dead mouse, plasticized mouse, and a human heart was performed and assessed.

**Results**

The 40-80 kVp pair was identified as the optimal DECT protocol, yielding a mean errors of 0.9 ± 2.6% on Zeffand 0.8 ± 1.8% on re; simulation results were similar.

**Conclusion**

We have implemented DECT for an optimal small animal imaging protocol, enabling tissue characterization for dose calculation of preclinical radiotherapy studies. Using known tissue-like materials for the DECT calibration are important aspects in achieving accurate DECT imaging.

**Figure 1 (A,B) Photos of the calibration and validation phantom; (C,D,E,F) Simulated and experimental images of the validation phantom; (G,H) Zeff and re images of the calibration phantom. The average noise within the CT images was 15HU.**

**SP018.5 - Low-dose prostate cancer brachytherapy by injections of radioactive gold nanoparticles (103Pd:Pd@Au NPs)**

**Author(s):** Myriam Laprise-Pelletier, Diane Djoumessi, Jean Laguex, Marie-France Côté, Marc-André Fortin

Axe Médecine Régénérative, Centre de recherche du centre Hospitalier Universitaire de Québec, Québec/CANADA

Here we report on the development of a new approach for low-dose prostate cancer brachytherapy, based on the injection of radioactive 103Pd:Pd@Au NPs. Photons emitted by the radioisotope palladium (103Pd; photon energy : 20.1 and 23.0 keV), interacting with gold distributed in the vicinity of and inside cells, are expected to lead to higher energy deposition compared with conventional low-dose brachytherapy. A rapid (~4h), one-pot procedure was developed to synthesize ultra-small 103Pd:Pd nanoparticles (radioactive precursor: 103PdCl2, MDS Nordion, Canada), followed by encapsulation with gold (Figure 1a-b; nanoparticle diam.: ~ 40 nm). Thus-obtained core-shell nanoparticles were stabilised with biocompatible polyethylene glycol (NH2-PEG-SH), purified and concentrated by centrifugation. The tumour retention of 103Pd:Pd@Au-PEG NPs was studied in a PC3 prostate cancer xenograft model (n = 11). For this, the NPs were labeled with a moderate (sub-therapeutic) labeling activity level (4 μCi 103Pd/mmol Au; 2 μL/ injection). The animals were CT-scanned immediately after implantation, then at time-points (1 and 8 days). The 103Pd:Pd@Au NPs injection sites were clearly
SP019 - Nanobiosensors and Nanotheranostics

SP019.1 - Synthesis and evaluation of C595 mAb-conjugated SPIONs nanoprob for specific detection of Prostate cancer 

Author(s): Mohammad Abdolahi1, Sophie Laurent1, Lionel Larbanoix2, Corine Sermeus2, Sebastien Boutry1, Robert N Muller2
1Persian Gulf Nuclear Medicine Research Center, Bushehr University of Medical Sciences, Bushehr/IRAN, 2General, Organic And Biomedical Chemistry, University of Mons, Mons/BELGIUM

Introduction: Carcinoma of the prostate is the most frequent diagnosed malignant tumor in men and is the second leading cause of cancer-related death in this group. Despite the efficacy of local therapy (surgery or radiation therapy) for treating localized disease, the cure rate is highly dependent on the stage of disease at the diagnosis and early detection of prostate cancer is key to designing effective treatment strategies. However, in its early stages, PC rarely causes symptoms and the majority of men diagnosed with advanced PC at the time of diagnosis. New detection methods are needed for prostate cancer, particularly for metastatic disease, in order to provide patients the best possible staging and treatment. The objective of the present study is to locate primary tumors or distant metastases using MRI with contrast agents targeted specifically to cancer cells. We take advantage of the fact that many types of prostate cancer cells express high levels of mucin 1 (MUC1) oncoprotein on their cell surface. The imaging strategy is to use superparamagnetic iron oxide nanoparticles (SPIONs), attached to an antibody that directly target MUC1, to specifically enhance the contrast of MUC1-expressing prostate cancer cells. The use of antibody-conjugated MRI contrast agents to specifically target cancer cells has been demonstrated previously for some other cancers. Here, we demonstrate an MRI contrast agent targeted specifically to the MUC1-expressing prostate cancer cells.

Methods: A number of cell lines were chosen for MRI experiments: DU-145 cells, which express a high level of MUC1, and LNCaP cells, which do not express MUC1. Conjugation of Mab C595 (anti MUC1) to commercial SPIONs (Micromod, 20 nm diameter) was achieved by using a heterobifunctional linker, sulfo-SMCC. LNCaP and DU-145 cells incubated with conjugated SPIONs. In vitro and in vivo imaging was performed in a 7 T MRI system.

Conclusions: Results of this study showed that through functionalization of SPIONs by C595 monoclonal antibody specific binding of the SPIONs to the MUC1-expressing cells is achievable. With development of this and similar imaging specific vehicles, more effective and detailed diagnosis of prostate cancer through high concentrations of SPIONs at the tumors site is possible.

Fig1. T2-weighted imaging of LNCaP cells (3×10^6) after 2h incubation with SPIO-C595 nanoprobe (Left) and DU145 (Right) at Fe concentration of 0, 5, 10, 20, 40, 80 µg/ml (The vial in the middle is PBS alone without any contrast agent).

SP019.2 - Magnetic Resonance Nanotheranostics of Guerin’s Carcinoma 

Author(s): Valeri E. Orel1, Thamos Mitrelias2, Marina Tselepi2, Eugeny Kruchkov1, Alexander Rykahlskiy1, Andry Romanov1, Tatjana Golovko1, Crispin H.W. Barnes1, Igor Shchepotin1
1Medical Physics & Bioengineering Research Laboratory, National Cancer Institute, Kyiv/UKRAINE, 2Cavendish Laboratory, University of Cambridge, Cambridge/UNITED KINGDOM

We proposed a new technology of nanotheranostics that is combination of magnetic resonance therapy and chemotherapy during moderate hyperthermia below 40 °C inside tumor with diagnostics by magnetic resonance imaging. As nanotheranostics agent the multifunctional magnetosensitive nanocomplex consisted of nanoparticles containing Fe3O4 with diameters < 50 nm and antitumor drug doxorubicin was used. The synthesis of multifunctional magno-sensitive nanocomplex was performed in a magnetomechanical reactor. We conducted a detailed imaging study of transplanted Guerin’s carcinoma in rats during treatment with magnetic nanotherapy. We showed that treatment with magnetomechano-chemically synthesized magnetosensitive nanocomplexes based on Fe3O4 nanoparticles conjugated with the antitumor agent doxorubicin and followed by irradiation with local electromagnetic irradiation resulted in a better outcome than treatment with conventional doxorubicin or treatment with magnetic nanocomplexes without electromagnetic irradiation. An analysis of magnetic resonance images obtained over time showed that the application of local electromagnetic irradiation did not alter the position of magnetic nanocomplexes in the tumor.

SP019.3 - Effects of Fluorescence Gold Nanoclusters on Anti-oxidation and Anti-aging by Cell Model 

Author(s): Walter H. Chang1, Wen Hsiung Chan1, Nai Ruei Cyue2, Cheng-An J. Lin2
1Department Of Biomedical Engineering, Chung Yuan Christian University, Taoyuan/TAIWAN, 2Department Of Biotechnology, Chung Yuan Christian University, Taoyuan/TAIWAN

We have developed gold nanoclusters (Au@DHLA, Diameter = 2nm) with red - NIR fluorescence and excellent biocompatibility as novel bioprobes. Moreover, we further found that Au@DHLA is not only a promising probe for cell labeling but also has the anti-oxidative stress properties and further improved cell viability. These novel findings indicate that Au@DHLA has a potential to reduce senescence and apoptosis. We observed the interaction of Au@DHLA with mouse osteoblasts, fibroblasts, and hepatocytes. Au@DHLA has been found to have rapid and efficient cell uptake into the mouse cells, although the toxicity analysis of mouse osteoblasts, fibroblasts and hepatocytes of the tolerance variation are not the same, but it is confirmed that Au@DHLA for mice cells has a good biocompatibility. In the experiment, we utilized the hydrogen peroxide that induced the increase of the oxidative stress of the mice cells then stained it with the dye (DCF-DA) and flow cytometry is used to observe Au@DHLA. We found the results of the intracellular oxidative stress in mice were reduced and the collagen detected in fibroblast production in the known Au@DHLA does not affect the production. In detecting the ability of Au@DHLA of calcification experiments, we found that the low concentrations of Au@DHLA do not affect the ability of osteoblast calcification. We also found hepatocytes can generate the cholesterol, however Au@DHLA does not affect the hepatocytes. These study results demonstrated that
Au@DHLA has high potential to be developed as nanomaterials with anti-oxidation, anti-apoptosis and anti-aging properties for the application in medical research, aesthetic medicine, and regeneration medicine.

SP019.4 - Nanoparticle-aided Radiotherapy for Retinoblastoma and Choroidal Melanoma

Author(s): Yucel Altundal1, Erno Sajo1, G. M. Makrigiorgos2, Ross Berbeco2, Wilfred Nawa2
1Physics & Applied Physics, University of Massachusetts Lowell, Lowell/UNITED STATES OF AMERICA, 2Radiation Oncology, DFCI/BWH/Harvard Medical School, Boston/UNITED STATES OF AMERICA

This work investigates the dosimetric feasibility of employing gold nanoparticles (AuNPs) or carboplatin nanoparticles (CNPs) to enhance radiotherapy (RT) treatment efficacy for ocular cancers: retinoblastoma (Rb) and choroidal melanoma (CM), during kV-energy internal and external beam radiotherapy. The results predict that substantial dose enhancement may be achieved by employing AuNPs or CNPs in conjunction with radiotherapy for ocular cancer using kV-energy photon beams. Brachytherapy sources yield higher dose enhancement than the external beam in kV energy range. However, the external beam has the advantage of being non-invasive.

SP019.5 - Nanoparticle enhancement of radiation dose: experimental confirmation using scintillation dosimetry

Author(s): David R. Mckenzie1, Marie Christine Zdora1, Paul Z.Y. Liu1, Natalka Suchowerska2
1School Of Physics, University of Sydney, Sydney/AUSTRALIA, 2Radiation Oncology, Chris O’Brien Lifehouse, Sydney/AUSTRALIA

Nanoparticles of high atomic number enhance the radiation dose delivered and therefore are potentially useful in radiation therapy. The effects of beam energy and nanoparticle size on dose enhancement have been modelled using Monte Carlo and the response of cells has been measured in-vitro. However, for different cell-lines a range of responses has been observed, which are not always consistent with the Monte Carlo predictions. The aim of this study is to provide a direct measurement of the dose enhancement that is independent of the cytotoxicity of the particles or the manner in which cells take up the particles.

A composite was made using commercially available liquid scintillator (BC430 or BC 498) and gold nanoparticles (diameter 30nm, Nanopartz Inc). The scintillation light emitted during irradiation was used to evaluate the enhanced dose from the photoelectrons emitted from the nanoparticles. The samples were exposed to radiation beams with a range of energies (50kV, 75kV, 100kV, 125 kV, 180kV and 280kV). Some of the emitted light was absorbed by the nanoparticles and this effect was corrected for. The scintillation light was coupled into a PMMA fibreoptic and transferred to a photo multiplier tube (PMT) for readout. The PMT was calibrated to dose after subtracting the background signal consisting of Cerenkov, fluorescent and stray light. A theory was developed using photon absorption cross sections taken from the NIST XCOM database (Berger et al 1998).

SP019.6 - Graphene Plasmonics as Promising Platform for Highly Sensitive Plasmonic Sensing

Author(s): Dong Ha Kim
Chemistry And Nano Science, Ewha Womans University, Seoul/ KOREA

Surface plasmon resonance (SPR) is the collectively oscillating charge densities at the interface between thin metal film and dielectrics in resonance with the incident light. SPR-based sensors have emerged as a versatile tool for the label-free and real-time biomolecule sensing during the recent two decades. However, it has been recognized that the sensitivity has yet to be improved to allow for single molecule detection. Incorporation of additional plasmonic nanostructures onto SPR sensor chip is one of the most promising strategies. The use of graphene in conventional plasmonic devices was suggested by several theoretic research studies. Plasmons in graphene were also intensively investigated by some researchers and tight confinement, tunability and long propagation which make graphene as a promising material for SPP-based optical nanodevice applications were reported. It is required to enhance the light-matter interaction for the actual applications despite of relatively high light absorption of single layer graphene. In this regard, the use of graphene in conventional plasmonic devices has been suggested. However, the existing theoretic studies are not consistent with one another and the experimental studies are still at the initial stage. To reveal the role of graphenes on the plasmonic sensors, we deposited graphene oxide (GO) and reduced graphene oxide (rGO) thin films on Au films by layer-by-layer self-assembly method and their refractive index (RI) sensitivity was compared for the first time in SPR-based sensors. The deposition of GO bilayers with number of deposition L from 1 to 5 was carried out by alternative dipping
of Au substrate in positively- and negatively charged GO solutions. The fabrication of layer-by-layer self-assembly of the graphene films was monitored in terms of the SPR angle shift. GO-deposited Au film was treated with hydrazine to reduce the GO. For the rGO-Au sample, 1 bilayer sample showed a higher RI sensitivity than bare Au film, whereas increasing the rGO film from 2 to 5 layers reduced the RI sensitivity. In the case of GO-deposited Au film, the 3 bilayer sample showed the highest sensitivity. The biomolecular sensing was also performed for the graphene multilayer systems using BSA and anti-BSA antibody.

SP020 - Biomedical Modeling

SP020.1 - Respiratory parameters have different patterns in imposed-inspiration and imposed-expiration within a closed pneumatic circuit in rats

Author(s): Fabio G. Aoki1, Marcelo H. Valenga1, Thiago G. Rodrigues1, Paulo F.G. Cardoso2, Rogerio Pazetti2, Henrique T. Moriya1

1Escola Politecnica, University of Sao Paulo, Sao Paulo/BRAZIL, 2Instituto Do Coracao, University of Sao Paulo, Sao Paulo/BRAZIL

Computer-controlled research ventilators for small animals (SAV) are often used to assess the respiratory mechanics’ parameters such as resistance and elastance of the respiratory system in animal models of disease. In commercially available SAVs, it is common to obtain such parameters with the forced oscillation of a given volume of air into respiratory system with a quasi-sinusoidal pattern in a closed pneumatic circuit (i.e. both the injection and the removal of gas during the piston movement). We hypothesized that obtaining the respiratory mechanical parameters with the linear single-compartment model (LSCM) during the forced inspiration and forced expiration (when calculated together) is not sufficient to explain the physiology of the respiratory system exposed to high doses of bronchial agonist. In order to verify this, male Wistar rats (n = 5) were anesthetized, orotracheally intubated, mechanically ventilated at 90bpm (or 1.5Hz) with a tidal volume of 10mL/kg, and a positive end-expiratory pressure (PEEP) was set at 3cmH2O. The ventilation was performed in a commercial mechanical ventilator (flexiVent, SCIREQ Inc., Canada) and the animals were infused with a saline solution (PBS), followed by 3 increasing doses (3, 30 and 300mg/mL) of the bronchial agonist methacholine (MCh). Respiratory parameters were calculated by the LSCM. Pressure and volume data, calibrated and corrected by a proprietary software, were analyzed using a computational routine. The full quasi-sinusoidal signal data was compared to inlet and outlet of air from the lungs separately. The data obtained showed that the difference among the three signals (i.e. whole signal, imposed-inspiration, and imposed-expiration) is pronounced at the higher dose (MCh 300mg/mL). Data from imposed-inspiration alone seem to better reflect the respiratory mechanics when a large dose of bronchial agonist is used.

SP020.2 - Autonomic and cardiovascular responses to food ingestion and gum chewing in healthy young subjects

Author(s): Kyuichi Niizeki, Tadashi Saitoh

Biosystems Engineering, Yamagata University, Yonezawa/JAPAN

Objective: Our previous study has demonstrated that in humans mental stress exerts an influence on the oscillations of respiratory sinus arrhythmia (RSA), inducing incoherent phase lag with respect to breathing in addition to a decrease in the amplitude of RSA1. It was suggested the enhanced sympathetic nerve activity during stress may modulate the transduction property of cardiac vagal efferent nerve. However, whether coherent oscillations of RSA could be altered by other physiological condition has not been shown. We hypothesized that dietary behavior may induce strong cardio-respiratory synchronization, because that the digestive organs are innervated by parasympathetic nervous system. In this study, we examined cardiovascular responses to eating solid food and chewing a tasteless gum, with special reference to whether the phase coherency of RSA is altered by dietary behavior.

Methods: After 5 min of rest, 14 subjects were asked to eat solid meal [maple flavored Calorie Mate (CM) ] at their own pace, which
was followed by 5 min postprandial recording. We also examined the separate effects of mastication on cardiovascular variables by chewing a tasteless gum (GM). We measured ECG by means of wireless electrocardiogram, beat-by-beat blood pressure (BP) by means of Finapres, and breathing activity by inductance plethysmography. The R to R interval (RRR) of ECG wave and respiratory movement signals were sampled with a frequency of 10 Hz. These signals were further band-pass filtered with the frequency range 0.1~0.5 Hz. Instantaneous phases and amplitudes of RSA and respiration were continuously calculated by Hilbert transform, and then phase coherence (λ) between RSA and respiration was computed. Beat-to-beat stroke volume (SV) was determined by the pulse-contour method. Cardiac output (CO) was SV times heart rate (HR). To assess autonomic activation, the low- and high-frequency components of heart rate variability (HRV) were computed by applying a fast Fourier transform by the Welch method.

Results and Discussion: From rest to CM, transient increase in BP and decrease in RRI were observed. A transient decrease in the latency between OAEs and ABRs were further compared. System of auditory propagation pathway, the OAEs and ABRs were the integrity and coherence. Based on the integrated detection results, the testing conditions might be changed, lacking of proofs to ensure simultaneously. When comparing the features between the signals, we suggest that phase coherence analysis of RSA could provide a sensitive measure for evaluating cardiac autonomic influences on dietary behavior compared to the conventional frequency analysis of HRV.

SP020.4 - Numerical Optimization Performance of a Perfusion Kinetic Modelling Algorithm using Volumetric DCE CT

Author(s): Igor Svistoun1, Catherine Coolens1, Catherine Coolens1

1Radiation Physics, Princess Margaret Hospital, Toronto/CANADA, 2Dept Radiation Oncology, University of Toronto, Toronto/ON/CANADA

Introduction: Dynamic-contrast enhanced (DCE) CT imaging is increasingly being used to quantify tissue vascular and functional properties for treatment response assessment by its combination with tracer kinetic modeling. However, clinical kinetic parameter results have been shown to be highly dependent on measurement input and analysis method. Implementing the parameter estimation algorithm involves many design decisions including choice of: data processing sampling rate, continuous-to-discrete system mapping approach and numerical optimization algorithm. As such a simulation framework was designed to investigate the effects of those choices, as well as effects of measured signal aliasing and noise on the accuracy and speed of the parameter estimation.

Methods: A widely-used 2-compartment model (modified Tofts) was chosen which describes the dynamic perfusion properties of a contrast agent using 4 parameters: Ktrans - transfer from blood plasma into extracellular extra-vascular space, Kep - transfer from extracellular extra-vascular space back to blood plasma, Vb - whole blood volume per unit tissue. To account for separation between injection and measurement site, a time delay τ must be added. The 4-parameter estimation from the measured data requires numerical optimization. A test framework was developed where an experimentally derived population-average arterial input function and randomly sampled parameter sets [Ktrans , Kep , Vb , τ] were used to generate tissue curves. Knowing the ground truth values, 5 numerical optimization algorithms were investigated using multiple starting points from a quasi-random set: sequential quadratic programming (SQP), downhill simplex (Nelder-Mead), pattern search (PS), simulated annealing (SA), and differential evolution (DE). This was repeated for two error function evaluation approaches – finite impulse response (FIR) and infinite impulse response (IIR) approximations of extended Tofts model and the impact of these approaches on speed and accuracy evaluated for sampling rates of 1, 10 and 100 Hz. DE algorithm was implemented on a GPU for speed improvement testing since processing even a modest area of 128x128x200 voxels would require days on the CPU.

Results: SQP, Nelder-Mead and DE produced good results on clean and noisy input data outperforming SA and PS in terms of speed and accuracy. During calibration, the best 3 algorithms did not exceed absolute error 9.4e-6% for any parameter. When run on typically aliased and noisy (sigma=6HU) data average absolute % errors were: Ktrans=11.96%, Kep=8.2%, Vb=25.7%, τ =3.6%. On average SA and PS took 1 and 2 orders of magnitude, respectively, slower to converge. We found IIR to approximate the model much better at sampling rates 10 times lower than those required for FIR approximation i.e. when upsampling same data and processing with FIR at 10Hz the average absolute error drops from [4.3%, 1.7%, 16.0%, 1.4%] to [4.3%, 1.7%, 6.6%, 0.3%] for each parameter. CUDA_DE runtime averaged at 3e-2 sec/voxel – a speed improvement of 199x over CPU_DE.

Conclusion: Evaluation of different optimization algorithms, sampling and noise scenarios indicated a preferred implementation of CUDA_DE. This will be extended to a clinical version with real-time analysis capabilities with ex-vivo kidney perfusion data presented at the meeting.

SP020.3 - Characteristic Analysis and Modeling for Signals of Auditory Propagation Pathway

Author(s): Qin Gong1, Xiaolin Li2, Tao Zhang3, Xi Chen1

1Biomedical Engineering, School of Medicine, Tsinghua University, Beijing/CHINA, 2Tsinghua National Laboratory for Information Science and Technology (TNList), Beijing/CHINA

Otoacoustic Emissions (OAE) and Auditory Brainstem Response (ABR) play important roles in the processing information of the auditory perception. Most previous studies only measured one signal simultaneously. When comparing the features between the signals, the testing conditions might be changed, lacking of proofs to ensure the integrity and coherence. Based on the integrated detection system of auditory propagation pathway, the OAEs and ABRs were measured simultaneously in normal subjects under different intensities and frequency of click and tone burst stimulation. The model to simulate the TEOAEs latency-frequency function was built up, and the latencies between OAEs and ABRs were further compared.
**SP020.5 - Validation of a Sympathovagal Balance Model to Evaluate Autonomic Function in Rats Using Time-Frequency Analysis**

**Author(s):** Rui Fonseca-Pinto¹, Lucília N. Diogo², Silvia V. Conde², Emilia C. Monteiro², Maria P. Guarino²  
¹School Of Technology And Management, Polytechnic Institute of Leiria, Leiria/PORTUGAL, ²Cedoc, Nova Medical School, Faculdade de Ciências Médicas, Lisboa, Portugal, Lisbon/PORTUGAL

The Autonomic Nervous System (ANS) activity can be evaluated in humans by using Heart Rate Variability (HRV) analysis through classical spectral analysis, and more recently by the use of newer techniques by time-frequency analysis. We have previously shown that Blood Pressure (BP) changes felt in HRV spectrum can be assessed and possibly isolated using a hybrid methodology in which HR and BP (in particular diastolic blood pressure) are mixed to produce an instantaneous variation energy plot reflecting the sympathetic and vagal autonomic activity, in other words, the ANS modulation on Heart Rate and Blood Pressure.

In this work we test the same approach in rats with the objective to validate the use of this methodology using continuous Blood Pressure recordings to evaluate the ANS changes.

Data were obtained in 20 rats by using telemetry probes implanted in the abdominal cavity and connected to the abdominal aorta for continuous BP and HR recordings in control situation and also in response to stimuli that change the autonomic response such as chronic intermittent hypoxia and drug administration.

The results showed that this hybrid methodology allows the evaluation of autonomic nervous system balance and can be used in laboratory and eventually in clinical settings to evaluate disautonomies.

**SP021 - Public Health, Active and Healthy Aging**

**TRACK 13: INFORMATICS IN HEALTH CARE AND PUBLIC HEALTH**

**SP021.1 - Informatics in Health Care and Public Health**

**Author(s):** Leandro Pecchia  
School Of Engineering, University of Warwick, Coventry/UNITED KINGDOM

**Learning objectives:**

Attenders non experienced in the study of falls will be introduced to the main challenges of this field and will be able to discriminate, interpret and classify interventions for: risk of falling assessment, fall detection, fall prediction and fall prevention.

Attenders will learn how physiological monitoring has been used to assess the risk of falling in the next few months.

Attenders will learn how physiological monitoring has been used to predict falls due to postural hypotension in the next few minutes.

**Abstract**

Falls are a major problem of later life, causing loss of independence and quality of life for senior citizen and their families. Falls are difficult to prevent, because caused by complex and dynamic interactions between hundreds of intrinsic (subject specific) and extrinsic (circumstance dependent) risk factors.

Multifactorial interventions seem to be most effective approaches to prevent falls, and includes simultaneously exercises, training, multifactorial home assessments, home safety interventions (i.e. elimination of specific risks) and vitamin supplementations. However, inform these interventions with accurate information about the risk of falling in the next few hours, days or weeks is needed in order to make those interventions more cost-effective and sustainable.

Several technologies have been proposed to support or inform these interventions. Many focused on fall detections using wearable sensors (mainly accelerometers and gyroscopes); unobtrusive sensors (i.e. cameras, Kinect, microphones) or ambient sensors (i.e. infrared or pulse-Doppler radar systems to detect motion or to monitor the ambient response to falls as floor vibrations). Fewer studies aimed to detect falls while happening in order to predict the impact (pre-impact fall prediction) and eventually reduce harms (i.e. inflating airbags). Some studies proposed technologies for the risk of falling assessment, using body-worn kinematic sensors or heel and toe clearance measurements.

However, recent studies proved that there are specific circumstances in which the probability of falling is much higher, especially in-door. For instance, the 30% of indoor falls happen while rising from beds or chairs and the risk of falling in specific hours of the day increases significantly.

This talk will present the preliminary result of two studies investigating for the first time how physiological monitoring and biomedical signal processing can support fall prevention intervention by assessing the risk of falling in the middle term (few weeks) and predicting in the short term (few minutes before) falls due to specific circumstances (i.e. rising from bed or chair). Two case studies will be presented in which Heart Rate Variability (HRV) was used to predict falls or to assess the risk of falling, proving that:
HRV resulted systematically depressed in fallers;

subjects with a depressed HRV showed a significantly increased relative risk of falling in the next few months;

monitoring the HRV in the 5 minutes before standing-up it is possible to predict postural hypotension, which is the main cause of falls happening while rising.

Finally, the preliminary attempts to integrate those predictive modeling in wearable and unobtrusive monitoring applications for falls prevention will be discussed.

SP021.2 - Monitoring Information System of Aedes Aegypti Reproduction
Author(s): Heleno S. Morais¹, Oziel S. Santos¹, Mateus A. Rocha¹, Tâssila Catarina S. Almeida¹, Lurdhes M. Brasil², Gerardo A. Idrobo³

¹College Gamma, University of Brasilia, GAMA/BRAZIL, ²Post-Graduate Program In Biomedical Engineering, University of Brasilia, Gama/BRAZIL

Aedes aegypti is a mosquito and main transmitter of dengue disease. Dengue is a viral disease that can only be transmitted to Humans by the bite of infected mosquitoes with the virus of the disease. It usually manifests in three clinical types, one of which can lead to death. The classical dengue, is classified as a febrile illness of mild to moderate intensity; dengue hemorrhagic fever, more severe than the last one, it comes to changes in blood clotting of the infected person; and dengue shock syndrome, very rare form, but can be fatal if not treated in time. Furthermore, Aedes aegypti transmits diseases like yellow fever, and it also has fully capacity to transmit chucunghua fever. Due to the fact that it is a fatal disease and the eradication of Aedes Aegypti is practically impossible, it is very important monitoring and control of Aedes Aegypti reproduction. The monitoring and control processes are still precarious when it comes to mosquito eggs counting technology collected through ovitraps vane in breeding sites. Because this processes are performed manually by experts using magnifying glass and tweezers. This paper presents a mechanism to make these processes faster and more efficient, it is a hardware / software interaction mechanism capable of capturing microscopic images of ovitraps vane and from an image processing software automating the counting of eggs contained in the vanes and in the future through geoprocessing inform the locations of higher reproduction of Aedes aegypti in a given region.

SP021.3 - Design and Functionality of a Meta-Reporting Tool within a Medical Devices Vigilance System
Author(s): Antonios Deligiannakis¹, Nikos Giatrakos¹, Aris Demitzakis²

¹Electronic & Computer Engineering, Technical University of Crete, Chania/GREECE, ²Biomedical Technology Unit, Dept. Of Medical Physics, School of Medicine, University of Patras, Rio, Patra/ GREECE

Medical Devices (MDs) are an important factor related to the quality of healthcare that patients receive. Although regulations have been applied and standards are imposed on MD manufacturing, faulty behavior incidents (referred to as adverse events) are frequently observed and reported by various organizations, such as FDA[1] and EUDAMED[2]. Given these reports, which include information about MD products associated with an adverse event, national healthcare authorities have the duty of examining whether listed products match the equipment of administered institutions and of contacting them with information about the potential risks that admitted patients (or users) may encounter. Subsequently, the individual healthcare institutions should cross-check, appropriately maintain, or even withdraw the potentially hazardous MD that they own.

To facilitate healthcare authorities promptly notifying institutions under their organizational chart about potentially hazardous devices, we have designed and developed a meta-reporting, web-based tool as a part of the MEDEVIPAS system. Our tool automatically generates meta-reports of matches of adverse event reports to inventoryed MD equipment and to disseminate these meta-reports to institutions in a user-friendly format, conceivable by non-expert (medical or paramedical) users, such as administrative hospital employees. Our tool receives as input information about MD inventories and crawled reports of adverse events. An entity matching algorithm is executed, matching medical devices in reports with those in MD inventories (and computing a matching score in each case) using the manufacturer, model and serial number of a MD, upon the insertion of new reports of adverse events (or of new MDs) in the system. From that point forward, our meta-reporting tool, which is the focus of this paper, provides the necessary functionality to registered users.

Meta-reports are created and made available to registered institutional users via a web application, in a tabular format. The meta-reports display information about potentially affected medical devices of each user, along with data from a related adverse event report, the matching score, etc. This information can also be provided in printable format using the web application. Email alerts are also created and forwarded to their registered accounts automatically upon the detection of a possibly matching device. The alerts are displayed prominently at our web-based tool and remain active until institutional users confirm that they became aware of the cited situations. Our tool also exploits user feedback on the validity of provided meta-reports, which is then incorporated in the entity matching algorithm to increase its accuracy performance (properly modifying the matching score of matched records). Apart from providing meta-reports, analysis capabilities are embodied in our tool in the form of aggregate statistics per MD manufacturer, MD group and registered institution.

Keywords: Medical Device, Vigilance, Adverse event, Reporting Tool

SP021.4 - Evaluation of the Impact in the Physical Condition of School Age Children Exposed to an Intervention of Exergaming in Montemorelos Mexico
Author(s): Alejandra Guillen-Peralta, Gerardo S. Romo-Cardenas, Raul Rodriguez-Antonio, Gener Aviles-Rodriguez

School Of Engineering, Montemorelos University, Montemorelos/ MEXICO

The current epidemiological situation of overweight and obesity in Mexico has been extensively documented and analyzed. Studies define the situation as a metabolic and inflammatory disease, of chronic course, multifactorial and with high impact on public health.

For the treatment of this multifactorial phenomenon, strategies have been proposed focused in the promotion and health education of the
target audience, seeking at medium- and long term, to prevent and eventually achieve the reduction of this epidemic situation. The school age population is particularly at high risk, with consequences ranging from psychological areas, school performance and organic malfunctioning that could emerge during the lifetime of the individual.

The overweight and obesity appears to be related to environmental factors such as sedentary lifestyle. The improvement of the physical condition through physical activity is a challenge in these new generations.

Considering the sociological features of school age population (6-12 years), their general technological familiarity implied in this age group and their tendency toward virtual interactions, an initiative of using video game platforms was designed performed, in order to promote physical activity (Exergaming). In addition, an evaluation of the impact in the physical condition on the participants through standardized anthropometric and physical performance tests was made, via pre and post testing. Results shows that there is a significant difference in variables related to flexibility, strength and body composition in a such a way, that opens the possibility to consider this type of virtual tools as an option for physical training in school age children.

SP020.5 - Using the EIP on AHA monitoring tool for the early technology assessment of a planned device to predict in-hospital falls in the elderly

Author(s): Christian E.H. Boehler1, Fabienne Abadie2, Lotte Steuten3, Leandro Pecchia4

1Joint Research Centre, European Commission, Seville/SPAIN, 2Panaxea bv, Enschede/NETHERLANDS, 3School Of Engineering, University of Warwick, Coventry/UNITED KINGDOM

In-hospital falls can lead to severe health consequences for the individual and are associated with substantial cost to health and care systems and it is estimated that up to one third of all in-hospital falls happen straight after standing up from a bed or chair. It is possible that a sudden drop in blood pressure shortly after rising is causative for many of these falls and a recent observational study suggested that the blood pressure after standing up can be predicted with high accuracy based on the ECG registered during the five minutes before rising (82.5% accuracy; false positive 10%; false negative 7.5%). This study aims to inform the design of a device that could warn patients about the immanent risk of falling based on a drop in blood pressure after rising in an early assessment of the health and economic outcomes of such a technology. The monitoring and assessment tool for the European Innovation Partnership on Active and Healthy Ageing will be used in order to predict the potential impact of such a device on the number of falls and subsequent health outcomes as well as the impact on healthcare utilisation. The tool rests on a three-state Markov process (including baseline health status, deteriorated health status (i.e. a fall) and death), which allows estimating the probability of patients having a post-fall event with severe health consequences. Health states will be valued using EQ-5D data from the literature and resource use will be estimated based on the documented consequences of falls in a UK hospital setting. The probability of a fall following a sudden drop of blood pressure and the likelihood to prevent a fall through an alarm triggered by such a drop in blood pressure during standing up will be elicited from a group of falls experts with various backgrounds, including participants of the EIP on AHAs Action Group A2 on falls prevention. Key drivers of health and economic outcomes of the planned intervention will be assessed through extensive sensitivity and scenario analyses. With this study we will not just be able to assess the potential impact of a planned warning device for the prevention of in-hospital falls, but also the value of the EIP on AHA monitoring tool for the early evaluation and the pre-market assessment of new and innovative health technologies.

SP021.6 - An innovative Decision Support System (DSS) for patients with Inflammatory Bowel Disease (IBD)

Author(s): Evaggelos C. Karvounis1, Vasilios E. Tsiolas1, Kallirroi Kyriaki1, Epameinondas V. Tsiolas1

1Research Laboratory Of Hepato-gastroenterology, Division Of Gastroenterology, Faculty Of Medicine, School Of Health Sciences, University of Ioannina, Ioannina/GREECE, 21st Division Of Internal Medicine And Division Of Gastroenterology, Faculty Of Medicine, School Of Health Sciences, University of Ioannina, Ioannina/GREECE

In IBD, investigators have suggested a possible role of various infective agents and recent epidemiological studies and veterinarian reports have reconsidered the pathogenetic role of some microbes and/or related vectors to the potential pathogenesis of some human disease. The etiopathology of IBD still remains unknown. The combined use of lifestyle surveys associated with blood samples and relevant clinical registers seems the best methodology to identify possible links between genetic predisposition, disease occurrence and natural course of the disease.

Such a system will help understand the natural course of the disease, study the predisposing factors and related genes and determine early clinical, genetic and immunological predictors of outcome and response to treatment. We build an efficient personal-ized web-based platform, in order to manage medical data, using efficient data mining and knowledge extraction techniques. Various variables already defined and determined for which associations are searched within the recorded datasets, discover interesting inter-relation and extract new knowledge from multiple and heterogeneous archived data that reflect everyday lifestyle and medical information, examine the results of previous therapeutic regimens and obtain quantitative explanations of the observations and generate efficient reports with intelligent data visualization.

We create an innovative clinical DSS, an efficient web-based platform, which incorporates 2 modules: Data Repository and Knowledge Discovery/Statistics module. The Data Repository module is a centralized data repository for annotation data (clinical, demographic and experimental data), sample source and handling information, processing and quality assurance information, as well as inventory and process flow data. In the front end, it will provide tracking, data query, report generation, process management functions, data handling as well as statistics, data mining and knowledge extraction capability (Knowledge Discovery and Statistics module incorporated in the back-end of the system). Moreover, the module will contain a Data Representation module that will handle the presentation of the extracted knowledge from the patients' data.

For the Data Repository module, a secure database has already been developed. For old patients, medical data from almost 600 patients, using their hard-copy medical records, have already been digitized. Blood sampling has already been achieved in 294 new patients and 234 healthy volunteers, while the results of the genetic and natural course of the disease.

For old patients, medical data from almost 600 patients, using their hard-copy medical records, have already been digitized. Blood sampling has already been achieved in 294 new patients and 234 healthy volunteers, while the results of the genetic (susceptibility gene polymorphisms) and serological (inflammatory and serological prediction markers) study are recorded in the database. Several knowledge discovery techniques have been applied in the Databases, giving more than satisfactory results.

Building such a system, for the first time in Greece, will contribute even more to IBD knowledge and research as the proposed sys-

tem will create a unique multidisciplinary combined database with combination of clinical, environmental and laboratory data in IBD. In addition, as IBD is regarded to be a multifactorial disease, we hope to better define some factors that clearly predispose to certain IBD phenotypes and IBD disease course. Finally, we hope that the computer-
ed platform will enrich our experience and will contribute towards a better IBD education and training in our medical, nursing and labora-
tory personnel and serve as a model and a basis for research in other chronic gastrointestinal and/or inflammatory diseases.

ABSTRACTS | IUPESM 2015 WORLD CONGRESS ON MEDICAL PHYSICS & BIOMEDICAL ENGINEERING
SP022.1 - Biomedical Engineering in Nigeria: A Developmental Overview

Author(s): Kenneth I. Nkuma-Udah, Eileen E.C. Agoha, Kennedy O. Ejeta, Gideon I. Ndubuka

Department Of Biomedical Engineering, Federal University of Technology, Owerri, Nigeria, Owerri/NIGERIA, Food Sciences And Technology, Abia State University, Uturu, Uturu/NIGERIA, Department Of Biomedical Technology, Federal University of Technology, Owerri, Nigeria, Owerri/NIGERIA

Biomedical Engineering (BME) activities in Nigeria can be said to have started in the 1970s during which collaborative efforts were made by engineers, medical doctors, pharmacists, physicists, technologists and other scientists. Although, the pace of development was hitherto slow, most efforts were in the arena of training - short courses, continuing education or professional development. However, the coming of NIBE in 1999 has propelled a steady progress of BME activities in Nigeria. BME activities in Nigeria was further given a big boost in 2007, when the first undergraduate programme in BME started in the Federal University of Technology, Owerri, Nigeria with NIBE contributing the foundation members of faculty. Established in 1999 with the vision “to develop and advance the biomedical science, health and human well-being of Nigeria through modern technological approaches comparable to those obtainable in any developed country of the world”. NIBE is currently structured in 5 divisions - biological engineering; medical engineering; clinical engineering; rehabilitation engineering; and biomedical physics / allied sciences - to accommodate virtually every field in the sciences. It had its 1st annual BME conference in 2000. Since then it has organised 9 national biomedical engineering conferences and 6 national professional development courses in Nigeria. In 2003, NIBE was admitted as the 50th member of IFMBE. The same year, she co-founded the African Union of Biomedical Engineering and Sciences (AUBES) in Ghana while some members were on a Medical Equipment Training. The role of NIBE in developing BME in Nigeria is mainly as a membership group to develop resources for BME by evolving adequate training programmes for members, facilitating accreditation and certification of professionals practicing BME in Nigeria.

SP022.2 - Modernising Scientific Careers – a new scheme for the education and training of physicists, engineers and other scientific staff in the UK National Health Service

Author(s): Keith Ison, Chris Gibson, Sarah Peel, Sue Hill

Medical Physics Department, Guy’s and St Thomas’ Hospital, London/UNITED KINGDOM, National School of Healthcare Science, Birmingham/UNITED KINGDOM, NHS England / Health Education England, Leeds/UNITED KINGDOM

Modernising Scientific Careers (MSC) is a UK-wide government initiative to address training and education of the NHS healthcare science workforce (2011). MSC provides a flexible career pathway to meet current and future health system needs via a single coherent training framework across 50,000 healthcare scientists of all disciplines including medical physicists and clinical engineers.

MSC covers all career stages, and the associated training and education programmes incorporate both academic and workplace-based training. Early training is broad based with greater specialisation in the more advanced programmes. The intent is to develop a skilled yet flexible workforce with sustainable education and training funding. It is already being developed to cover Medical Physics Experts and public health scientists.

The MSC career pathway has four stages and qualifications (2014a):

- Assistant and associate training – vocational qualifications for scientific support roles

- Practitioner Training Programme (PTP) – BSc for healthcare science practitioners

- Scientist Training Programme (STP) – Masters for clinical scientists

- Higher Specialist Scientific Training (HSST) – five year doctoral level programme for consultant clinical scientists (2014b)

The presentation will outline evidence-based approaches to trainee selection, progress monitoring and assessment and also report initial outcomes. MSC is competency-based and scientists and engineers often approach competencies in a linear fashion, breaking complex real-world scenarios into discrete tasks with defined right answers that do not fully reflect clinical reality or capture all necessary learning. In progressing from academic achievement to professional competence, we propose that trainees should be encouraged to document real workplace processes, acknowledge and reflect on uncertainty, and develop strategies to respond appropriately. These documents would encourage all staff to consider reflective practice as integral to professional competence.

Competencies and Expectations of the Candidates, as They Came Allotted Time. However, We Faced Many Challenges in Terms of the That All Residents Undergo the Same Learning Modules During the Qualified Medical Physicists. The Structure of the Program Is Such Certified Physicists with the Objective of Graduating Clinically Established at Our Institution. The Program Is Supervised by Board Center, Riyadh/Saudi Arabia

**SP022.3 - Medical Physics Residency Program in Developing Countries: Lessons, Challenges and Solutions Learned from a Regional Pilot Training Program**

*Author(s):* Shada Wadi-Ramahi, Waleed Al-Najjar, Belal Mofthah

Biomedical Physics, King Faisal Specialist Hospital and Research Center, Riyadh/Saudi Arabia

A regional 2-year structured program in medical physics was established at our institution. The program is supervised by board certified physicists with the objective of graduating clinically qualified medical physicists. The structure of the program is such that all residents undergo the same learning modules during the allotted time. However, we faced many challenges in terms of the competencies and expectations of the candidates, as they came from different countries in the region. MSc level candidates exhibited varying levels of academic competencies, and the clinical expectation varied by country; From conventional treatments using Co-60 to state-of-the-art treatments on linacs. Challenges faced include how to cover various academic deficiencies, which required time-consuming per needed lectures, another major challenge was how to transition Co-60 users into linac users while dealing with other residents who wanted to advance more in linac-based techniques. A third major challenge was how to evaluate the various competencies achieved at the end of the 2 years, given the starting level and background, of course many other challenges presented themselves during the years. In this paper, we present a detailed description of our residency program, the modules it contains and expected competencies, then we discuss in more details the challenges we faced given the heterogeneous mix of the residents and the solutions that evolved, and still is evolving, to overcome these hurdles. Residency programs covering many countries, in which one cannot control education levels, have to evolve and adapt in order to produce useful results. A one-size-fits-all formula found in North America, for example, will fail if copied as is and implemented in developing countries.

**SP022.4 - International Union of Biological Sciences**

*Author(s):* Nils Chr. Stenseth

Université Paris Sud XI, IUBS, Orsay/FRANCE

The International Union of Biological Sciences (IUBS) was established in 1919. IUBS is presently composed of 27 National Members and 80 Scientific Members. The role of IUBS is to promote the study of biological sciences, to initiate, facilitate and coordinate research and other scientific activities necessitating international, interdisciplinary cooperation, to ensure the discussion and dissemination of the results of cooperative research, particularly in connection with IUBS scientific programmes. IUBS sponsors the organization of conferences and also scientific programmes. The current IUBS programmes are dealing with climate change, bionomenclature, Disaster and biodiversity, and also a case study on Bees and Coffee.

The bio-cluster meeting will be a good opportunity to discuss how the different bio-unions programmes and activities could interact for the benefit of our community. On the other hand, it is important to develop our interaction with ICSU and with its programme Future Earth. The bio-cluster of ICSU should discuss and propose ways to improve our participation in this important ICSU programme.

**SP022.5 - Promoting the public image of Medical Physicists and Biomedical Engineers**

*Author(s):* Michael Cheng

Biomedical Engineer, Ottawa/ON/Canada

This paper focuses on the alert raised by the IUPESM President that “In many developing countries, there are no physicists or engineers in clinical settings; in developed nations, physicists and engineers are losing their positions in hospitals.” The author offers his personal viewpoints derived from the past 30 years in more than 30 developed and developing countries around the world working on medical device regulations and management issues. The conclusion proposed collaborative summit brainstorming.

Despite their technical talent and devotion to their work, most medical physicists (MP) and biomedical/clinical engineers (BME/CE) have less skills in promoting themselves to the public. I think this phenomenon is a weakness that needs to be addressed. We know that industries and some politicians will hardly succeed if they do not make themselves known to the public. The professions must seek ways to promote their public image. I will describe two domains where the merits of the MP and BME/CE are huge but under recognized by the public: 1. MP, BME/CE are principal builders of healthcare technology; 2. MP and BME/CE play vital roles in patient safety.
with medical devices in healthcare facilities. Then, I will propose outreach to developing countries with references to simple knowledge transfer tools described in two education sessions offered by this Congress WC2015. Lastly, I will suggest examples of opportunities for research to help emerging global health issues, and opportunities to develop personal medical technologies to empower personalized medical care and encourage patient responsibility. A full paper is also submitted with this abstract; the descriptions in the full paper also make references to four other submissions (see below) to this Congress WC2015.

In order to promote the public image of MP and BME/CE, the hurdles to overcome are complex; therefore an appropriate strategy to “market” their huge contributions to global healthcare should be a key topic for collaborative summit brainstorming called by the President.

SP022.6 - The Utilization and Design of Doorless Mazes for Medical Linear Accelerator Rooms In Ontario, Canada
Author(s): Joseph J. Szabo
Walker Family Cancer Centre Physics, Niagara Health System, St. Catharines/CANADA

Medical linear accelerator rooms in typical cancer centres use mazes for radiation protection, but these are usually short and straight and still require a heavy shielding door at their entrance. Especially for treatment energies higher than 10 MeV the purpose of the door is to attenuate both photons and neutrons that have scattered down the maze, as well as capture gamma rays created by neutrons in the concrete walls, ceiling, floor, and ultimately in the door itself. This radiation must be dealt with to secure the therapy staff working in the control area near the room entrance. Depending on the length of the maze, the door may have to attenuate scattered photons, moderate fast and intermediate neutrons, and finally attenuate capture gamma rays. This requires often massive and cumbersome doors, which usually consist of an initial layer of lead to attenuate the scattered photons and the maze generated capture gamma rays, followed by another layer of quite thick, highly hydrogenous material such as borated polyethylene, to moderate fast and intermediate energy neutrons into low energy thermal neutrons, which then are effectively captured by the boron, while only releasing capture gamma rays of a relatively low energy (0.473 MeV). A final layer of lead at the outside of the door is used to block these capture gamma rays. All this is usually quite heavy, resulting in a door that is 10’s of centimeters thick and thousands of kilograms in weight, often requiring tracks and motors to operate, which makes it quite expensive. Also, moving such a heavy door is usually slow and since the door is likely opened and closed more than hundred times a day, it is prone to wear, requiring expensive continuous maintenance. And in the event of a breakdown a manual technique for opening must be available. All this can be avoided if one uses a longer maze. In 1991 the author designed a maze that required no door at all. This maze was first put into clinical use in the city of Kingston and was the first maze without a door in the province of Ontario. After the successful implementation of this design, it was utilized in all new clinics and many of the older clinics in all of Ontario. In addition, it has been used elsewhere in Canada as well as in parts of the United States. However, in other parts of the world the doorless bunker is still not very well known. This paper is a review of the extent of the use of this design as well as detailed instruction on how to build it to minimally take up real estate by use of multiple bends and strategically placed polyethylene and borated polyethylene panels to reduce the neutron flux well before it reaches the maze entrance. Calculation methods and measurements from the radiation survey for the most recent construction will be shown. In that case the results were so good that the author was actually concerned that his survey meters were not functioning.
**SP023 - Quantitative Imaging: Part 1**

**SP023.1 - Improving quantitative functional imaging with dynamic contrast enhanced studies using a linearized Johnson-Wilson model approach**

**Author(s):** Fiona Li1, Ting Yim Lee2

1Department Of Medical Biophysics, Western University, London/ON/Canada, 2Lawson Health Research Institute, London/ON/Canada

**Background**

The standard two compartment (2-C) model, consisting of vascular and tissue compartments, is frequently used to fit tissue time density curves (TDCs) from dynamic contrast enhanced (DCE) CT or MR studies. However, the compartmental assumption for the vascular space means that the finite vascular transit time is ignored. As image acquisition speed increases beyond 0.5 Hz, parameters estimated by fitting the tissue TDC with the two 2-C model without accounting for the finite vascular transit time could be biased. Also, 2-C model is unable to estimate blood flow (F), it estimates Ktrans instead, which is the flow extraction efficiency product. On the other hand, fitting tissue TDC using the Johnson-Wilson model with the adiabatic approximation (aaJW) will provide estimates of both Ktrans and F that are independently important for investigations of tumor associated angiogenesis. Current applications of the aaJW model use non-linear curve fitting methods to estimate Ktrans and F. These methods are prone to be trapped in local minima while searching for the optimal fit to the tissue TDC resulting in erroneous estimates of model parameters.

**Purpose**

To develop a method to linearize the fitting of DCE tissue TDC with the aaJW model and compare the method’s sensitivity to model parameters and covariances of estimated parameters with non-linear fitting methods.

**Method**

Linearization of 2-C model fitting of tissue TDC has been published before but no attempts to-date have been made for linearization of aaJW model fitting. The method we developed to linearize aaJW model fitting of the tissue TDC is based on time integrals of the arterial TDC (Cp(t)) and the tissue TDC (Q(t)). The stability of the linear and non-linear fitting methods were analyzed using sensitivity analysis which calculated the changes in the fitted tissue TDC with changes in the model parameters or sensitivity functions of both fitting methods. The sensitivity functions were used to estimate the covariances of the estimated parameters for both methods.

**Results**

The equations for tissue TDC fitting with the aaJW model are:

Non-linear: \( Q(t) = F \cdot [D(t-to) - D(t-to-W)] + K1 \cdot Cp(t-to-W) \cdot \exp(-k2 \cdot t-to-W) \)

Linear: \( Q(t) = F \cdot [D(t-to) - D(t-to-W)] + K1 \cdot D(t-to-W) + F \cdot k2 \cdot [E(t-to) - E(t-to-W)] \cdot k2 \cdot G(t) \)

where * is convolution operator, to is the delay between Q(t) and Cp(t), W is the vascular transit time, K1=Ktrans, k2 is backflux rate constant, D(t) is the integral of Cp(t), E(t) is the integral of D(t) and G(t) is the integral of Q(t). The sensitivity functions for the linear fitting method were ~ 5 times larger than those of the non-linear fitting method resulting in the covariances of estimated parameters from the linear fitting method > 1.3 times less than those of the non-linear fitting method.

**Conclusions**

Unlike the non-linear fitting method, the linear method estimates model parameters at the unique global minimum sum of squared deviations between the fitted and the measured tissue TDC. More importantly, the covariances of the estimated model parameters are significantly less for the linear method than the non-linear method. This would lead to more precise quantitative functional maps from DCE studies and more reliable diagnosis.

**SP023.2 - Early tumor Response assessment using volumetric DCE-CT and DCE-MRI in Metastatic Brain Cancer Patients**

**Author(s):** Catherine Coolens1, Brandon Driscoll1, Warren Foltz2, Cynthia Menard1, Gelareh Zadeh1, David Jaffray1, Carolin Chung1

1Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/Canada, 2Division Of Neurosurgery, University Health Network, Toronto/Canada

**Introduction:** Early change in tumour vascularity following stereotactic radiosurgery (SRS) is a potential biomarker of response. Dynamic contrast enhanced (DCE) MRI is often used to interrogate perfusion but has known limitations to accuracy and precision. Progress in CT technology now allows for volumetric acquisition with 4D temporal dynamic analysis (TDA) of perfusion. As such, DCE-CT presents as a standard for tracer-kinetic validation. This study aims to compare DCE-MRI analysis against DCE-CT support with 4D temporal dynamic analysis (TDA) of perfusion. As such, DCE-CT presents as a standard for tracer-kinetic validation. This study aims to compare DCE-MRI analysis against DCE-CT support.

**Methods:** Patients with brain metastases (total of 14 tumours) treated with SRS as part of REB-approved clinical trials underwent volumetric DCE-CT (Toshiba, Aquilion ONE) and DCE-MRI (IMRIS 3T Verio, Siemens) scans at baseline then 7 and 21 days post-SRS. DCE-CT parameters were: 80kV, 100mAs, 1sec interval and 0.468x0.468x1mm. VFA T1 quantification and DCE MRI acquisitions used 3D-FLASH with matching echo times (1.86 msec), repetition times (4.8 msec), and geometric features (1.15x1.15 mm in-plane resolution, 40 slices at 1.5 mm each). DCE-MRI used a 20° flip angle, and 45 frames were acquired every 5.8 sec. Voxel-based whole brain TDA was performed on both DCE-CT and DCE-MRI data using in-house software. Perfusion, permeability and Area-under-the-Curve (Ktrans, Ve, AUC) were assessed within each tumour at every time point using the Modified Tofts model and a linear regression analysis which calculated the changes in these parameters over treatment. Correlation between these vascular parameters and treatment response, evaluated as stable or reduction in tumor volume was assessed.

**Results:** At Day 21 only one tumor had a volume that remained larger than at baseline while the other tumors showed a decrease in volume of (mean of 53.6 +/- 31%). **DCE-CT:** 3 of 8 stable or responding tumours revealed a Ktrans reduction of 44.6 +/- 36.6% (p=0.056) at Day 7 post-BS while 10 out of 13 responding tumours had a reduction in Ktrans of 26.0 +/- 16.6 % by Day 20 (p < 0.01). Only one of the non-responding tumours showed a decrease in Ktrans at Day 7 while none did at Day 20. **DCE-MRI:** 7 of the 8 stable or reducing tumours revealed a Ktrans reduction of 17.4 +/- 16.6% (p<0.05) at Day 7 post-BS while 10 out of 13 responding tumours had a reduction in Ktrans of 24.0 +/- 20.3 % by Day 20 (p < 0.05). MRI results showed weak overall correlations with DCE-CT at either Day 7 (R2=0.16) or Day 20 (R2 = 0.21) for Ktrans. AUC changes did not correlate significantly with either time point or modality.

**Acknowledgement:** This research was fully funded by the Canadian Cancer Society (Geriatric Cancer Research Project).
Conclusions: This is the first study evaluating perfusion parameters acquired by same-day volumetric DCE CT and DCE MRI in a cohort of metastatic brain patients. The weak correlation between MRI and CT results may reflect issues such as sensitivity to arterial input, tumour type, definition of response, and edema that are under further investigation. These early results show Ktrans reduction at day 20 may predict for eventual tumor response post-SRS.

**SP023.3 - Diffusion tensor imaging is correlated with quantitative histology in surgically-resected hippocampi of epilepsy patients**

**Author(s):** Maged Goubran1, Boris Bernhardt2, Charlotte Blinston1, Diego Cantor-Rivera1, Jonathan C. Lau1, Robert R. Hammond4, Sandrine De Ribaupierre2, Jorge G. Burneo1, Seyed Mirsattari3, David A. Stevens2, Andrew G. Parrent1, Andrea Bernasconi2, Neda Bernasconi2, Terry Peters1, Ali R. Khan5

1Imaging, Robarts Research Institute, London/ON/CANADA, 2McConnell Brain Imaging Center, Montreal Neurological Institute, Montreal/QC/CANADA, 3Epilepsy Program, Clinical Neurological Sciences, Western University, London/ON/CANADA, 4Pathology, Division Of Neuropathology, Western University, London/ON/CANADA, 5Medical Biophysics, Western University, London/ON/CANADA

**Introduction**

Hippocampal sclerosis (HS) is the most common pathology seen in mesial temporal lobe epilepsy (MTLE) patients, and studies have shown a relationship between the pattern of sclerosis and post-surgical outcomes (seizure freedom and memory impairment). Thus, predicting these pathological sub-types pre-operatively can play a significant role in pre-surgical management of TLE patients. Diffusion tensor imaging (DTI) has shown to be a sensitive marker of microstructural changes but the precise relationship of diffusion markers with HS subtypes is not well known. The current study aims to assess these relationships by comparing pre-operative imaging with quantitative markers of neuropathology from histology of the tissue resected after surgery.

**Methods**

Patients (N=15) undergoing temporal lobectomy were recruited for this study and imaged pre-operatively in a 3T MRI using a research protocol that included diffusion tensor imaging (41+6 directions, 2.5mm isotropic resolution). Tissue was resected en-bloc and prepared for histological processing. Histology slides were cut, stained with H&E, NeuN (neuronal marker) and GFAP (glial marker) for quantitative histology assessment. Hippocampal subfields (CA1, CA2/3, CA4/DG) were manually segmented in the pre-operative MRI and histology slides, and spatial correspondences were found using our validated MRI-histology image registration pipeline. Automated histology image processing was performed to extract maps of neuron density, size, and gliosis, and were correlated against mean diffusivity (MD) and fractional anisotropy (FA) of the corresponding slice.

**Results**

Histological data for two subjects were discarded due to insufficient tissue to assess delineate the subfields, thus correlations were computed with 13 patients. Mean diffusivity (MD) in the end folium (CA4/DG) was significantly correlated with the number of neurons in CA4 (r=-0.833, p<0.001) and the size of neurons in CA4 (r=-0.841, p=0.039). An increase in the extracellular space could explain the significant increase in MD in samples which contained fewer neurons or neurons with smaller average size.

**SP023.4 - Evaluation of fully automatic volumetric GBM segmentation in the TCGA-GBM dataset: Prognosis and correlation with VASARI features**

**Author(s):** Emmanuel Rios Velazquez1, Raphael Meier2, William D. Dunn Jr3, Brian Alexander4, Roland Wiest4, David A. Gutman2, Mauricio Reyes2, Hugo J.W.L. Aerts3

1Radiation Oncology, Dana-Farber Cancer Institute | Harvard Medical School, Boston/UNITED STATES OF AMERICA, 2Institute for Surgical Technology and Biomechanics, Bern/SWITZERLAND, 3Department Of Biomedical Informatics, Emory University School of Medicine, Atlanta/GA/UNITED STATES OF AMERICA, 4Institute for Diagnostic and Interventional Neuroradiology, University Hospital Inselspital and University of Bern, Bern/SWITZERLAND

**Background:** Reproducible definition and quantification of imaging biomarkers is essential. We evaluated a fully automatic MR-based segmentation method by comparing it to manually defined sub-volumes by experienced radiologists in the TCGA-GBM dataset, in terms of sub-volume prognosis and association with VASARI features.

**Methods:** MRI sets of 67 GBM patients were downloaded from the Cancer Imaging archive. GBM sub-compartment were defined manually and automatically using the Brain Tumor Image Analysis (BraTumIA). Spearman’s correlation was used to evaluate the agreement with VASARI features. Prognostic significance was assessed using the C-index.
Additionally, auto-segmented sub-volumes showed higher correlation with the manually delineated volumes (range ($r$): 0.65 – 0.91).

Results: The auto segmented sub-volumes showed high agreement with the manually delineated volumes ($r$: 0.65 – 0.91). Additionally, auto-segmented volumes showed higher correlation with the VASARI features ($r = 0.35, 0.50$, and 0.59; manual $r = 0.29, 0.50, 0.43$, for percentages of contrast-enhancing, necrosis and edema, respectively). The relative contrast-enhancing volume and the post contrast abnormal volume (necrotic core + contrast enhancing region) showed the highest C-index (0.73 and 0.72), comparable to manually defined volumes ($p = 0.22$ and $p = 0.07$, respectively). The non-enhancing region defined by BraTumIA showed significantly higher prognostic value (CI = 0.71) than the tumor-associated edema (CI = 0.60), both of which could not be separated by manual delineation.

Conclusion: BraTumIA tumor sub-compartments showed higher correlation with VASARI data, and equivalent performance in terms of prognosis compared to manual sub-volumes. This method can enable more reproducible definition and quantification of imaging based biomarkers and has a large potential in high-throughput medical imaging.

SP024 - Breast CAD and New Breast Imaging Techniques

SP024.1 - Modelling Breast Cancer Tissue via Analysis of WAXS Signatures

Author(s): Robert J. Leclair

Physics, Laurentian University, Sudbury/CANADA

A wide-angle x-ray scatter (WAXS) method to quantify the composition of cancerous tissue is described. The modeling of cancerous tissue is accomplished by analysis of the differential linear scattering coefficients $\mu_s$ of fibro glandular (fib) $[\mu_s,\text{fib}]$, cancerous breast tissue ($\mu_s,\text{cancer}$) and water ($\mu_s,\text{h2o}$). A model assumed that cancer consisted of fib and a volume of cancerous cells. Most of the scattering properties of the cells can be attributed to water since cells are composed primarily of water. In this work, the volume of cancerous cells was approximated by a volume of water. A two basis function method was used to estimate the $\mu_s$ of cancer, namely $\mu_s,\text{cancer}(x) = \text{afib} \cdot \mu_s,\text{fib}(x) + \text{ah2o} \cdot \mu_s,\text{h2o}(x)$ [Eq. 1], where $\mu_s,\text{fib}(x)$ and $\mu_s,\text{h2o}(x)$ are the basis functions, afib and ah2o are coefficients. The variable $x = (1/\lambda) \sin(\theta/2)$ is the momentum transfer which combines dependence of scatter on x-ray wavelength ($\lambda$) and scatter angle $\theta$.

A system of 78 equations corresponding to $x$ values ranging from 0.80 to 3.2 nm$^{-1}$ was constructed. The coefficients afib and ah2o of this overdetermined system were calculated via least-squares using the singular value decomposition (svd) method. The coefficients were also used to estimate fractional volumes $v$ of fib (afib) and h2o (vh2o), namely $v_{\text{fib}} = \text{afib}/(\text{afib} + \text{ah2o})$ and $v_{\text{h2o}} = \text{ah2o}/(\text{afib} + \text{ah2o})$.

These $v$ values were then used to estimate another more meaningful $\mu_s$ estimate of cancer given by $\mu_s,\text{cancer}(x) = v_{\text{fib}} \mu_s,\text{fib}(x) + v_{\text{h2o}} \mu_s,\text{h2o}(x)$ [Eq. 2]. For one set of diffraction data, afib = 0.23, ah2o = 0.73, $v_{\text{fib}} = 0.24$ and $v_{\text{h2o}} = 0.76$ and for the other set afib = 0.83, ah2o = 0.31, $v_{\text{fib}} = 0.73$ and $v_{\text{h2o}} = 0.27$. For the first set of data both $\mu_s$ estimates (i.e. Eqs. 1 and 2) matched the measured $\mu_s$ cancer well whereas for the latter only the $\mu_s$ via Eq. 1 provided a reasonable match. The modeling of cancerous tissue via analysis of WAXS signals is an interesting method to learn more about the characteristics of cancer. It was not surprising to see differences in predictions when using different WAXS data for breast tissue since they were different in the first place. The different results obtained justify the needs for more studies on the acquisition of WAXS signals of breast tissue. The presence of fat tissue could have affected the WAXS signals. In a future work, a WAXS fat subtraction protocol will be implemented in order to measure the $\mu_s$ coefficients of fib and cancerous tissue without the effects of fat. The measurements of $\mu_s$ for cells will also be done. Such data will help in characterizing the make-up of cancer and help determine the potential diagnostic use of WAXS.

SP024.2 - Analysis of 80 kV WAXS Measurements with a CdTe Breast Biopsy Diffractometer

Author(s): Nancy Mcdonald, Robert J. Leclair

Physics, Laurentian University, Sudbury/CANADA

The wide-angle x-ray scatter (WAXS) signatures of breast tissue may provide an additional source of diagnostic information in the realm of breast diagnostics. Measurements to test the ability of exploring a larger momentum transfer $x$ space with a custom built breast biopsy CdTe diffractometer were performed. 80 kV 3.2 mm diameter beams of 3 min duration interrogated 5 mm diameter, 2 to 5 mm thick samples of polymethyl methacrylate (PMMA) and polycarbonate as well as a 5 mm thick water sample. Scattered spectra $N_s(E)$
were detected at θ=6° with a 25 mm² x 1 mm thick CdTe detector. A 3 mm diameter aperture placed 4 cm above the detector yielded a solid angle of detection Ω = 4.9×10⁻⁵ sr at the sample center. The probed x range was from 0.3 nm⁻¹ to 3.38 nm⁻¹. Linear differential scattering coefficients μ were calculated via a semi-analytical model and compared qualitatively with μ calculated using coherent form factors and incoherent scatter functions from the literature. Because of the use of a higher kV beam, the effects associated with florescence escape and hole tailing in the CdTe crystal were investigated via the application of a detector response function. The incident spectrum N0(E) was estimated via application of the scatter model N0(E). The μs and compared qualitatively with μs scattering coefficients μs

Breast Cancer is the most common cancer in women worldwide. As mammographic double interpretation is not possible everywhere, and with the number of cases rising in addition to time and cost constraints, the development of Computer Aided Detection (CAD) systems with high sensitivity and high specificity is important. Mammographic breast density refers to the prevalence of fibroglandular tissue as it appears on a mammogram and it is an important breast cancer factor risk. Furthermore, breast density may mask abnormalities and/or lower the sensitivity of mammography. The development of density specific CAD systems coupled with automated breast density classification may alleviate the problem by achieving high sensitivity and specificity for certain breast density classes. Women with high breast density may seek supplementary screening – in addition to mammography. Amplitude-Modulation Frequency-Modulation based features have been successfully used to characterize mammographic breast density and to automatically classify mammograms into one of the four Breast Imaging Reporting and Data Systems (BI-RADS) mammographic breast density classes.

This work, presents initial results on the use of multi-scale Instantaneous Amplitude (IA), Instantaneous Phase (IP) and Instantaneous Frequency (IF) information from Amplitude-Modulation Frequency-Modulation (AM-FM) decomposition for the classifications of Regions of Interest (ROIs) from low density mammograms to either normal or cancerous/malignant. A Gabor filter-bank using eight orientations and six different frequency scales is applied for AM-FM demodulation. Dominant component analysis is used for the evaluation of IA, IF and IP at each frequency scale. The IA amplitude reflects local image intensity variations, e.g. edges, with different spatial scale variations reflected in different frequency scales whilst the IF measures local frequency content. First and second order statistical features are evaluated on each of the normalized histograms of the components across the different scales and are used for characterizing the ROI. Support Vector Machines (SVMs) are used for ROI classification.

All mammograms from the Mammographic Image Analysis Society Database that are classified as fatty are used for the development and the evaluation of the presented CAD system. Regions of different size - segmented using block processing from the mammograms classified as normal-, and the ROIs that hold biopsy proven malignancies (well defined masses, speculated masses, other ill-defined masses, architectural distortion and asymmetry but not calcifications) are used for training the SVM classifier. The SVM with RBF kernel is investigated using tenfold cross validation in order to identify the best parameters. The developed CAD system achieves accuracy over 80%, with sensitivity over 85% and specificity over 75% for all types of masses. The prediction results, achieved using the SVM classifier, are very encouraging. Similar CAD systems using different AM-FM with additional texture features will be developed and evaluated specifically for other mammographic density classes.

SP024.4 - Single Scatter Signals during Dual Detector Volume-of-Interest Breast Cone-Beam Computed Tomography: A New Source of Diagnostic Information?

Author(s): Curtis Laamanen, Robert J. Leclair

Physics, Laurentian University, Sudbury/CANADA

Dual detector breast volume-of-interest (VOI) cone-beam computed tomography (CBCT) is a technique that uses two scans to generate higher quality details of a VOI. A full field scan is acquired at low exposure with a flat panel detector whereas a high resolution scan of the VOI is acquired with a high resolution CMOS detector at higher exposure. The data obtained at lower exposure/resolution is used in conjunction with the higher quality VOI data to reconstruct images. The effects of scattered x rays on details within the VOI are reduced by this technique. In this work it is proposed that during the high resolution scan it could be beneficial to also use the flat panel detector to capture some scattered photons from the VOI for diagnostic purposes. Simulations were performed to assess the potential use of the single scatter that could be captured during the high resolution scan. A 14 cm diameter 10.5 cm long cylinder with an embedded 2 cm diameter spherical lesion was considered. Fibroglandular (fib) and water spheres were chosen to represent benign and cancerous lesions. The following percent mass compositions for the cylinder were considered: 80(fib):20(fat), 60:40, 50:50, 40:60, and 20:80. The distance from the source to isocenter was 58 cm and from the isocenter to detector plane 28 cm. Using a 60 kV beam with an HVL of 3.7 mm Al, energy integrated signals (EIS) were computed for each of the 300 × 300 1 mm² pixels. In normal full field breast CBCT, a typical mean glandular dose of 6 mGy is used. In this work, the VOI scan had an exposure 4× higher than that of the regular full-field CBCT. The incident cone beam irradiated the smallest VOI which included the spherical lesion. The EIS due to scatter (EISs) from the VOI were calculated for both fib and water lesions embedded in the different cylinder compositions. Since contrast reversal occurred across the detector, the information content was increased by adding pixels selectively. Pixels including signals from primary photons were not included in the summations. The variances in pixel signals were based on the propagation of Poisson noise in ideal energy integrating pixels. The signal-to-noise ratio in terms of EISs for malignant versus benign lesions within cylinders of the same composition were on the order of 20 thereby suggesting potential usefulness of the x-ray scattered photons. A problem
that needs to be addressed, however, is that there were significant variations in signals as a function of cylinder composition for a given lesion type. A study which includes a method to estimate the composition of the main phantom will be conducted.

SP024.5 - Investigating automatic techniques in segmentation accuracy of masses in digital mammography images
Author(s): Kareem D. Marcomini, Homero Schiabel
Dept Of Electrical Engineering, University of São Paulo, São Carlos/ BRAZIL

Many procedures have been developed to aid in the early detection and diagnosis of breast cancer. In this context, Computer-Aided Diagnosis (CAD) schemes were designed to provide to the specialist a reliable second opinion. In such schemes there is a complex step which corresponds to the segmentation since good structures classification is dependent on the features extracted from the segmented images. In this work we propose the use of several methods of automatic segmentation of breast lesions, such as: watershed, fuzzy c-means, k-means, Self-Organizing Map (SOM), Enhanced Independent Component Analysis Mixture Model (EICAMM) and level set. In order to evaluate which of them could provide more accurate results in segmenting breast masses segmented images were compared with those manually delimited by an experienced radiologist. Ten quantitative measures were obtained from the images. These segmentation techniques were applied on different types of lesions, including images corresponding to dense breasts. From the evaluation the level set technique has proved being more effective for the images set used to testing all the methods. It has registered a higher overlap rates in relation to the image segmented by the specialist as well as low rates of under and oversegmentation, reflecting in the high accuracy and low false-positive and error rates.

Step 3. If MI converges, end the registration process for the nth IR image.

Fig. 2 shows the well registration results between the 1st IR image and the nth IR image.

SP024.6 - The Automated Marker-Free Longitudinal IR Breast Image Registration Algorithm
Author(s): Chi-En Lee, Chung-Ming Chen
Institute of Biomedical Engineering, National Taiwan University, Taipei/TAIWAN

Longitudinal IR image registration is a very difficult task in general because it is impractical and unlikely to keep markers attached on a body surface of a subject for weeks or even longer. To overcome this problem, the new longitudinal IR image registration algorithm (Genetic Particle Competition, GPC), which is the first automated marker-free longitudinal IR image registration algorithm in the world for breast IR images and may be easily extended to other parts of the human body. The algorithm is based on two novel types of fiducial points, which are the corner points of heat patterns and the other is the branch points of the skeletons of heat patterns, and automated determination of corresponding pairs of fiducial points between two images. Suppose two IR images, namely, the 1st IR image and the nth IR image, are registered as depicted on the top of Fig.1. After finding the initial corresponding points by SIFT and deriving the corner points of heat patterns and the branch points of the skeletons of heat patterns, the GPC mechanism operates to find the corresponding point as follows:

Step 1. Randomly generate a set of candidate points around the initial corresponding point, which form the competitors.

Step 2. For each of the competitors on the deformed nth IR image are calculated the mutual information (MI) between the 1st IR image. Define the competitor with the maximal MI as winner, those ranked the top 50% of MIs as the selected competitors, and replace the remaining losers by new randomly generated competitors until the MI of the winner converges.
With the advent of MRI-guided radiotherapy, radiation dosimetry in the presence of magnetic fields must be addressed in several ways to assure accurate dose delivery and patient safety. To calculate dose accurately in these conditions, the only known method capable of simulating the transport of charged particles in dense matter in the presence of magnetic fields is Monte Carlo. At the present time, general-purpose codes such as PENELOPE and GEANT4 already offer this option and other codes, such as EGSnrc, remain under development. To assure the accuracy of Monte Carlo results, algorithms must be tested in conditions relevant to radiation dosimetry, such as ionization chamber response to radiation dose. To achieve the same rigorous benchmark as does the Fano cavity test, it is necessary to explore the conditions under which it can be performed in the presence of a magnetic field distribution.

This theoretical study is based on Fano's approach and evaluates the possibility to achieve charged particle equilibrium in heterogeneous media having uniform atomic properties. The Boltzmann transport equation, modified to include the Lorentz force, forms the basis of the theory. Two special conditions for the source and magnetic field distributions are evaluated as potential candidates for new Fano cavity tests. The applicability of Fano's theorem in these conditions is shown and the energy deposition is also derived from first principles.

Using the modified transport equation, it is demonstrated that the two proposed conditions on the source and the magnetic field allow Fano's theorem to apply. Moreover, the energy deposition under these conditions is shown to be identical to the one in the absence of a magnetic field, such as in a cavity dose calculation under standard Fano conditions.

This theoretical study demonstrates two possible conditions under which Fano's theorem is applicable in the presence of a magnetic field. While it was previously shown that in general, Fano's theorem cannot hold in the presence of a uniform magnetic field as it does not scale with mass density, this study is a significant improvement towards benchmarking Monte Carlo codes coupling radiation transport with magnetic fields.

**Material and Methods:** Recently our Clinac-2100CD Varian linear accelerator was upgraded to high dose rate Flattening Filter Free (FFF) 6MV X-rays for Stereotactic Radiosurgery. Beam parameters measured from minimum 2x2cm² to 40x40cm² field. As VMAT/IMRT based Stereotactic Radiosurgery comprises of many small segments, Penumbra modeling play a major role in final dose calculation. Both AAA & Acuros-XB algorithms allow users to fine tune the primary source spot size (SSS) so that computed beam profile penumbra can match with the measured beam penumbra for all the field sizes. SSS were varied from 0 to 2mm in steps of 0.5mm in X&Y direction. For each SSS, dose was calculated for open field sizes of 3x3cm², 5x5cm² & 10x10cm² and was analyzed with measured beam parameters. To evaluate beam modeling a water phantom (size=40x40x40cm³) was created and dose was calculated for different fields & for different SSS. The profiles at dmax and 10cms depth were taken for penumbra analysis with respect to measured profile. For all the SSS & field sizes Distance (in millimeters) to agreement (DTA) were performed between computed & measured 80% isodose curves. Similarly for Acuros-XB algorithm the average DTA at Dmax for SSS of 0.5, 1, 1.5, 2.0mm were -0.74±0.73, -0.74±0.73, -0.57±0.67, -0.03±0.64, 0.08±0.63 mm respectively. Similarly for Acuros-XB algorithm the average DTA at Dmax for SSS of 0.5, 1, 1.5, 2.0mm were -0.71±0.59, -0.71±0.59, 0.20±0.28, 0.34±0.31, and 0.62±0.38 mm respectively. The average DTA at D10 for SSS of 0.5, 0.5, 1, 1.5, 2.0mm were -0.52±0.65, -0.52±0.65, -0.15±0.75, -0.09±0.78, 0.11±0.79 mm respectively. Stereotactic treatment plan analysis shows that average PTV mean dose variation with SSS 0.75mm for AAA was found -2.0% compared to 1.0mm default SSS, whereas Acuros-XB SSS 1.2mm variation -1.2% compared to default 1.0mm. Absolute dose measurement results using small volume ion chamber and predicted plan dose variation for VMAT stereotactic plans found very minimal with AAA SSS 0.75mm and Acuros-XB SSS 1.2mm compared to algorithm default SSS.

**Conclusion:** For AAA algorithm the results shows a good agreement between measured dose and calculated dose for spot sizes of 0.5-1mm. On the other hand for Acuros-XB algorithm, a spot size of 0.5-1mm agrees better for the field size up to 5x5cm² & a spot size of 1-1.5mm agrees better for the field size greater than 5x5cm². Algorithms showed good agreement with measurement for range of fields provided primary source spot configuration has been adequately tuned for precise dose calculation and delivery.

**SP025.3 - A Geant4 Helical Tomotherapy model as a tool for 3D dose distribution evaluation**

¹INESC TEC, Porto/PORTUGAL, ²Technology And Health Department, Istituto Superiore di Sanità, Rome/ITALY, ³Medical Physics Unit, Ircss, Arcispedale Santa Maria Nuova, Reggio Emilia/ITALY

Very high technological level is involved in Helical Tomotherapy (HT). The gantry rotation, couch speed, dose rate and accurate MLC leaf positioning are crucial for accurate dose delivery. For a high quality and safe treatment, a machine Quality Assurance (QA) program and patient-specific dose verifications are requested. The most detailed
SP025.4 - Development of 4D actual delivered dose calculation system for dynamic tumor-tracking irradiation with a gimbaled linac
Author(s): Yoshitomo Ishihara1, Akira Sawada2, Nami Ueki1, Nobutaka Mukumoto1, Mitsuhiro Nakamura1, Yuki Miyabe1, Yukinori Matsuo1, Takashi Mizowaki1, Masaki Kokubo1, Masahiro Hiraoka1

(1) Purpose
In previous works, we have developed an in-house integrated four-dimensional (4D) Monte Carlo (MC) dose calculation system as a routine verification tool for dynamic tumor-tracking (DTT) irradiation. The purpose of this study was to develop 4D actual delivered dose calculation system for DTT irradiation by gimbals mechanism with Vero4DRT.

(2) Method
First, plans were created for five patients having lung cancers under the normal protocol for DTT. Furthermore, the modified DTT plans were created in consideration of several errors such as intrafractional mechanical, positional predictive, and overall targeting errors during DTT irradiation. These errors were retrospectively computed from orthogonal fluoroscopy images and the system log files stored during DTT irradiation. Subsequently, 4D MC dose calculation was performed with 6-MV photon beam delivered by the Vero4DRT using EGSnrc for both the original and the modified DTT plans, respectively. At that time, phase-space data at each respiratory phase was created from the particle data under the MLC with or without the above errors, respectively. Next, 4D dose distribution was created by summing up the dose distribution under the geometrical combination of the target and the MV beam at each respiratory phase. The dose distribution computed with the above errors was regarded as the delivered dose distribution during DTT irradiation while the dose distribution computed without the above errors was regarded as the planned DTT dose distribution. Finally, isodose curves and DVHs were compared between the planned DTT and the delivered DTT dose distribution.

(3) Result
For all cases, 2D gamma passing rate was 93% using criteria of 2% / 2 mm for each dose distribution on the axial, sagittal, and coronal planes at the isocenter, respectively. CTV coverage, mean dose within the lung, and maximum dose within the spinal cord were comparable between the delivered DTT and the planned DTT dose distribution.

(4) Conclusion
We have developed 4D actual delivered dose calculation system for DTT irradiation using the gimbaled x-ray head. The result has demonstrated that DTT irradiation with Vero4DRT achieves the dose delivery with high accuracy.

SP025.5 - Organ Doses from Hepatic Radioembolization with Y-90, Sm-153, Ho-166 and Lu-177: A GEANT4 Monte Carlo Simulation Study
Author(s): Nurul A.A. Hashikin1, Chai Hong Yeong2, Susanna Guatelli2, Basri Johan Jeet Abdullah1, Kwan Hoong Ng1, Alessandra Malardot2, Anatoly Rozenfeld2
1Department Of Biomedical Imaging, Faculty Of Medicine, University of Malaya, Kuala Lumpur/MALAYSIA, 2Centre For Medical Radiation Physics, Faculty Of Engineering And Information Sciences, University...
Introduction—Y-90 radioembolization are increasingly used for palliative treatment of advanced liver cancer. Since its physical decay is fully via beta emission, imaging following the treatment is rather challenging. Radionuclides with both beta and gamma emissions have been explored as alternative to Y-90 in liver radioembolization, however little information was available in terms of internal radiation dosimetry.

Materials & Methods—Monte Carlo simulation using GEANT4 source code was carried out. The GEANT4 advanced example human_phantom was used. A mathematical female phantom was adopted with organ geometries as specified in MIRD Pamphlet 5. A medium size, spherical hepatic tumor with radius, r = 4.3 cm was modelled within the liver volume. Y-90 sources were isotropically distributed within the tumor with total activity of 1.82 GBq determined using Body Surface Area (BSA) method recommended by SIRTex (Sydney, Australia) for the Y-90 therapy. The dose was calculated in all the organs of the human phantom. The simulation was carried out with the assumption of no lung and extrahepatic shunting, with full localization of Y-90 sources within the tumor volume. The resulting tumor dose was validated by comparing it with the dose calculated using partition model. The simulation study was repeated substituting Y-90 with Sm-153, Ho-166 and Lu-177. GEANT4.9.6.p03 was used.

Results—The 333 cm³ tumor volume corresponded to 18% tumor involvement. The tumor and normal liver tissue doses for the Y-90 simulation were (262.9 ± 0.6) Gy and (2.9 ± 0.1) Gy, respectively. In order to deliver tumor dose equivalent to 1.82 GBq Y-90, approximately 8.32, 5.83, and 4.44 GBq were required for Sm-153, Ho-166 and Lu-177, respectively. Doses to other organs were mainly dependent on the gamma energies (Figure 1). All the organ doses did not exceed 1 Gy.

Discussions—Although the organ doses deriving by Sm-153 and Lu-177 were relatively higher compared to Ho-166 and Y-90, the doses were still far below the maximum tolerance limit commonly used in radiotherapy, i.e. 60, 23 and 17.5 Gy for adrenal glands, kidneys and lungs, respectively. Alternative treatment with Sm-153 or Lu-177 is still feasible as long as the organ tolerance limit were not exceeded.

Conclusion—Ho-166, Lu-177 and Sm-153 offer the advantage of emitting useful gammas for post-procedure imaging. They show potentials as Y-90 substitutes for liver radioembolization, delivering a comparable tumor dose, and doses within the maximum tolerance limit to the surrounding organs.
ABSTRACTS | IUPESM 2015 WORLD CONGRESS ON MEDICAL PHYSICS & BIOMEDICAL ENGINEERING

Conclusions:
The Acuros XB algorithm performs well for calculating doses for 6 MV FFF beams in and around lung-like inhomogeneities, and shows better agreement with measurements than the AAA algorithm. In bone-like material, it shows good agreement in calculating the dose to medium, but differences above 5% were found in the calculation of dose to water.

Figure 2

SP025.7 - Performance of the ACUROS™ dose calculation algorithm for 6 MV FFF beams in inhomogeneous media
Author(s): Matthew Schmid1, Tony Tekel2
1BC Cancer Agency- Centre for Southern Interior, Kelowna/BC/CANADA, 2BC Cancer Agency- Centre for Southern Interior, Kelowna/CANADA

Purpose:
FFF beams are now commonly used in radiation therapy treatment. Because of the high dose rate that these beams typically offer, they are often used for stereotactic body radiotherapy (SBRT) of the lung. Accurate dose calculations are particularly important in these cases due to the high fractional doses delivered. In this study, the accuracy of Varian's Acuros XB dose calculation algorithm is investigated in inhomogeneous phantoms for both open fields and VMAT treatments.

Methods:
Three series of tests were performed using three different phantoms. ACUROS calculated doses were compared to Monte Carlo (MC) calculations, the anisotropic analytical algorithm (AAA), and film measurements. The phantoms were comprised of water equivalent material, lung equivalent material, and bone equivalent material. In one series of tests, the doses at various depths in slabs of lung and bone material embedded in solid water were evaluated. A second series of tests evaluated the 2D dose distribution in planes containing inhomogeneity boundaries, and a third set of tests used the QUASAR™ phantom (Modus Medical Device Inc.).

Results:
The depth-dose calculations in a slab of lung material embedded in solid water showed good agreement between the Acuros XB, MC, AAA, and measured values. The calculated depth dose values in a slab of bone embedded in solid water calculated by AAA agreed well with the measured values. Acuros calculated depth doses to medium showed excellent agreement with Monte Carlo calculations (dose to medium) and good agreement with film measurement, but differences above 5% were found in the calculation of dose to water with measurements. Monte Carlo calculations were repeated with the Gafchromic film simulated by a thin layer of water and showed excellent agreement with measurements. The 2D dose distributions calculated using the Acuros XB algorithm showed substantially better agreement with measurement than the AAA calculations (Figure 1 a,b,d and e). This was also true for the dose calculations in the lung phantom and for VMAT plans on the QUASAR phantom (Figure 1 c and f).

Conclusions:
The Acuros XB algorithm performs well for calculating doses for 6 MV FFF beams in and around lung-like inhomogeneities, and shows better agreement with measurements than the AAA algorithm. In bone-like material, it shows good agreement in calculating the dose to medium, but differences above 5% were found in the calculation of dose to water.

SP025.8 - Ray Tracing Algorithm for Virtual Source Modelling based on Evaluation of Rounded Leaf End Effect of Multileaf Collimator
Author(s): Dong Zhou, Hui Zhang, Peiqing Ye
Department Of Mechanical Engineering, Tsinghua University, Beijing/CHINA

Rounded leaf end effect of multileaf collimator plays a role in penumbra characteristics of dose profile. It strongly influences dose target volume conformity and organ at risk sparing for radiation therapy. Previous studies have shown that parameters in virtual source model could be fitted using dose distribution results obtained from Monte Carlo simulation or dosimetric measurement. However, there is a lack of research in literature reporting on virtual source modeling with the rounded leaf end effect incorporated. In this study, we present an analytical method for virtual source modeling by evaluation of the rounded leaf end effect of multileaf collimator on dose profile. We confine our study to single source modeling, with source energy distribution of Gaussian shaped. Ray Tracing algorithm is introduced and parameter estimation is conducted to revise the source size. Model verification is performed with numerical simulation, which is conducted based on the Monte Carlo codes of EGSnrc/BEAMnrc. It is shown that Ray Tracing algorithm employing the focal spot size of photon source would result in reduced penumbra width, compared with the simulation counterpart. This observation is probably related to the aperture effect of multileaf collimator. In contrast, results of penumbra width and radiation field edge offset using revised source size obtained with parameter estimation agree well with Monte Carlo simulation. In summary, the method we propose could provide insight into virtual source modeling using Ray Tracing algorithm.
SP026 - The Development of a Device for the Fricke Dosimetry for HDR Brachytherapy

Author(s): Camila Salata, Mariano G. David, Carlos E. Dealmeida

HDR-BT is considered an important option for cancer treatment, but the calibration of the Ir-192 is complex. The Fricke dosimetry has been considered an option to determine the absolute absorbed dose to water. It is composed mainly of water and ferrous sulfate, and the ferric ions in the solution will be converted to ferrous ions by the ionizing radiation, proportionally to the absorbed dose into the solution. The optical density of the solution is measured using a spectrophotometer. As this is a liquid dosimeter it is important to have a device where the solution will be irradiated. Some characteristics of the device should be considered: the wall material should be water equivalent and shouldn’t react with the solution; it must be sealed, but easy to vert the solution from the vessel into a cuvette to read it with the spectrophotometer. The main purpose of this study was to develop a device for the irradiation of the Fricke solution, using the HDR-BT Ir-192 sources.

Figure 1: Evolution of the devices created for the Fricke Dosimetry.

The first device created (Figure 1A) consisted of two glass balloons, one inside the other. The solution was disposed in the space between the balloons. The source was positioned in the center, inside a glass tube so it didn’t have any contact with the solution. Some measurements were done, and the disadvantages of this device were: the glass material wasn’t water equivalent; and the solution wasn’t homogeneously irradiated, as the distance from the source wasn’t the same on all the irradiated solution. The device was redesigned to improve the measurements (Figure 1B). The main changes were: the wall material was water equivalent, PMMA; the solution volume irradiated was only a central ring, so the solution was homogeneously irradiated. More measurements were done and it was very difficult to fill the device with the solution, and also difficult to vert the solution to the cuvette. The current device (Figure 1C) is a cylinder ring, where the solution is disposed and have corrected those problems. The source position is now calculated to be at the center of the ring. Now it is easier to fill it with the solution, and to vert the solution to the cuvette. Those improvements of the device are very important to the development of the Fricke dosimetry as an option for the Ir-192 sources calibration.
SP026.2 - A New Methodology for the Determination of the G-value for Fricke Dosimetry
Author(s): Camila Salata1, Leo D.O. Franco2, Mariano G. David3, Carlos E. Dealmeida1
1Dbb, Universidade do Estado do Rio de Janeiro, Rio de Janeiro/BRAZIL, 2Dbb, UERJ, Rio de Janeiro/BRAZIL

The Fricke dosimeter is a chemical dosimeter and its base is the ferrous sulfate. It is one of the most widely used chemical dosimeters and has been considered as a possible dosimeter for the determination of the primary standard for the absorbed dose to water of Ir-192 High Dose Rate brachytherapy (HDR-BT) sources. The Fricke dosimeter is mainly composed of water, so its attenuation of radiation is very similar to the water, which turns possible its use as an absolute dosimeter. During the interaction of the radiation with the Fricke solution the ions Fe²⁺ are converted to Fe³⁺, and this conversion is proportional to the absorbed dose at the solution. One of the parameters used to determine the absorbed dose at the Fricke solution is the chemical yield, known as the G-value. The G-value can be defined as the number of molecules of Fe³⁺ produced per joule of energy absorbed in the solution. This parameter has been determined by different authors, for different energies, but those data are old, and the methodology used was based on interpolations. This study proposes a new methodology for the determination of the G-value for Ir-192 HDR-BT sources. On the methodology proposed it was used a PMMA phantom (figure 1A) filled with water with three supports of PMMA for the Fricke solution, one for the ion chamber, and one for the Ir-192 source in the center (figure 1B).

Figure 1: A) PMMA Phantom with the supports for Fricke solution, ion chamber and Ir-192 source. B) The positioning of the supports in detail.

The position of the supports were fixed for each irradiation, and changed clockwise direction, after each irradiation. The source was always fixed in the center of the support. After each irradiation the optical density of the solution was read using a Micronal spectrophotometer. The absorbed dose in the Fricke solution at each position was considered equal to the dose determined by the ion chamber and Ir-192 source. During the interaction of the radiation with the solution the ions Fe²⁺ are converted to Fe³⁺, and this conversion is proportional to the absorbed dose at the solution. The results will be repeated using a new spectrophotometer recently acquired by the LCR, with better resolution and sensibility. This will improve the uncertainties associated with the measurements.

SP026.4 - IAEA Dosimetry Laboratory support to the IAEA/WHO SSDL Network
Author(s): Igor Gomola, Istvan Csete, Ladislav Czap, Joanna Izewska, Ahmed Meghzifene
Nuclear Sciences And Applications, International Atomic Energy Agency, Vienna/AUSTRIA

The IAEA Dosimetry Laboratory (DOL) is the central laboratory of the IAEA/WHO Network of Secondary Standards Dosimetry Laboratories (SSDLs). In 1976, the IAEA in collaboration with the WHO established this Network to provide a forum in which national SSDLs could regularly perform measurement comparisons and thus strengthen confidence in radiation dosimetry coherence worldwide. This Network, through its 84 SSDL members designated by Member States, provides a framework to establish a direct link between national dosimetry standards to the international measurement system (SI) of standards and the dissemination of SI quantities and units to end users through the proper calibration of field instruments by the SSDLs.

A Quality Management System (QMS) has been established for the DOL following the guidelines of EN ISO/IEC 17025:2005 standard. In 2005, the Joint Committee of the Regional Metrology Organizations (JCRB) and the Bureau International des Poids et Mesures (BIPM)
formally acknowledged that the DOL QMS satisfies the requirements of the Mutual Recognition Arrangement established by the Committee for Weights and Measures (CIPM-MRA) . Since that time, the 23 different calibration capabilities of the DOL are peer reviewed regularly; they are internationally accepted, and published in the frame of the CIPM-MRA.

The activities of the IAEA include an inter-laboratory comparison programme (for air kerma, Kair, and absorbed dose to water, Dw, in Co-60 beam, and Kair for diagnostic X-ray beam qualities) that enables the participating SSDLs to harmonize their calibration practices for measuring instruments used for the determination of different dosimetry quantities in line with the IAEA Codes of Practice TRS-398 and TRS-457. (Figure 2. shows the results for Kair and Dw in Co-60 beam )

In addition, the IAEA offers training opportunities in radiation dosimetry, calibration of dosimetry standards dosimetry audits, and quality management for SSDL staff from Member States. The training of SSDL staff contributes to the improvement of measurement capabilities in radiation dosimetry for radiation therapy, diagnostic radiology and radiation protection applications of ionizing radiation in IAEA Member States.

Examples of our work include:

- The activities of the IAEA include an inter-laboratory comparison programme for air kerma, Kair, and absorbed dose to water, Dw, in Co-60 beam, and Kair for diagnostic X-ray beam qualities that enables the participating SSDLs to harmonize their calibration practices for measuring instruments used for the determination of different dosimetry quantities in line with the IAEA Codes of Practice TRS-398 and TRS-457. (Figure 2. shows the results for Kair and Dw in Co-60 beam )

- In addition, the IAEA offers training opportunities in radiation dosimetry, calibration of dosimetry standards dosimetry audits, and quality management for SSDL staff from Member States. The training of SSDL staff contributes to the improvement of measurement capabilities in radiation dosimetry for radiation therapy, diagnostic radiology and radiation protection applications of ionizing radiation in IAEA Member States.

**SP026.6 - Monte Carlo corrections for a Fricke-based standard of absorbed dose to water for Ir-192 HDR brachytherapy.**

**Author(s):** Ernesto Mainegra-Hing

Measuring Science And Standards, National Research Council of Canada, Ottawa/CANADA

**Purpose:** Ir-192 HDR Fricke dosimetry requires a conversion factor dose to Fricke to air-kerma to determine the G-value of a 250 kV x-ray beam, and several correction factors to obtain the dose to water at the reference position. These factors can be determined using Monte Carlo (MC) techniques.

**Methods:** The G-value for an Ir-192 source is determined by interpolation between the G-values of two known beam qualities, Co-60 and 250 kV x-rays. The G-value of the 250 kV x-ray beam is determined by irradiating a bag with Fricke solution of known volume with a 250 kV beam of known air-kerma. A conversion factor dose to Fricke to air-kerma, DF/Kair, is calculated using the EGSnrc user-code cavity combined with a BEAMnrc model of the x-ray source. Knowledge of the Ir-192 G-value makes it possible to measure the dose imparted to a Fricke dosimeter placed at the reference position, immersed in a water phantom. The dose to water at the reference position is derived from the dose to Fricke by applying a conversion to dose to water, DFW, and several corrections to remove the effects of the holder, catheter, and beaker materials (Pwall), and to correct for volume averaging (Kdd). These corrections are determined with the EGSnrc user-code cavity by modeling the microSelectron V2 Ir-192 HDR seed used in our lab and the measuring setup in detail.

**Results:** DF/Kair is the largest factor required, with a value of 1.15 [0.06%]. This large value can be explained mostly by the mass
energy absorption coefficient ratio Fricke to air which is about 1.11 [0.02%] as determined using the EGSnrc user-code g. An Awall calculation with the user-code cavity shows that the rest of this correction factor is due to the contribution from secondary particles to the dose to Fricke (Awall=1.036 [0.002%]). Volume averaging contributes the second largest correction, which is about 1.015, while the wall correction and the Fricke to water conversion factor almost cancel out.

Conclusions: MC simulation can be used to determine the corrections required for HDR Fricke dosimetry. The large value of the Fricke to air-kerma conversion factor can be explained by the difference between the mass energy absorption coefficients for the Fricke solution and air. Remaining differences are caused by the contribution from secondary particles. The factor needed to obtain dose to water at the reference position from the dose to a Fricke dosimeter is significantly smaller and mainly due to volume averaging. Future work will focus on the sensitivity of these corrections to systematic uncertainties in the cross sections used for the MC calculations.

Method

The third party evaluation of absorbed dose to water has been performed between the Tokyo metropolitan hospitals and the Tokyo Metropolitan University (TMU) since 2007. In order to investigate the changes between the JSMP01 and 12, the absorbed dose at calibration depth Dc was evaluated. Absorbed dose measurement was performed separately by the stuff of the facilities and the TMU on the same day. Ionization chamber (TN30013, PTW), electrometer (Inovision 35040), digital quartz barometer (745-16B, Paroscientific), digital thermometer (TL1-A, Thermoprobe) and 1D water phantom (WP1D, IBA) was used for the third party evaluation and own equipment was used for the user evaluation.

Results

Before 2011, mean deviation from Dc evaluated by TMU and its standard deviation (1σ) were from 0.5 % to 0.7 % and from 0.5 % to 0.7 %, respectively. By the investigation in 2013-2014, ND,w and JSMP12 was adopted in 7 of 11 facilities. By analysis using the result of 7 facilities, mean deviation and its standard deviation was reduced to 0.1 % and 0.4 %, respectively. As a result, there is significant difference in mean deviation and variance (p < 0.05) between JSMP01 and 12.

Conclusion

In this report, it was observed that the deviation and variance between user and third party evaluation of Dc was reduced. Therefore it is confirmed that uncertainty of absorbed dose to water evaluation is reduced by adoption of the ND,w calibration and the new dosimetry protocol JSMP12.

SP026.8 - A calibration system of therapy-level dosimeter in Japan organized by ANTM

Author(s): Suoh Sakata1, Wataru Yamashita1, Nobuhiro Takase1, Masahiro Hoteida1, Yosuke Sasaki1, Hiroaki Okumura1, Hideyuki Mizuno1, Katuhisa Narita2, Akiyumi Fukumura2 1Dose Calibration Center, The Association for Nuclear Technology in Medicine, Chibashi/JAPAN, 2Research Center For Charged Particle Therapay, National Institute of Radiological Sciences, Chibashi/JAPAN

In Japan, the therapy-level dosimeter calibration had been carried out in terms of exposure until 2012. Therefore, the conversion factor kD,X was necessary to convert the calibration factor Nx obtained via air measurement to the absorbed dose calibration factor ND,w. In 2011, Japanese National Standard Laboratory (National Metrology Institute of Japan, NMIJ) established the national measurement standard of therapy level absorbed dose to water of Co60 and started to deliver this standard. According to the NMIJ activity, the ANTM (Association for Nuclear Technology in Medicine, the SSDL in Japan) has launched a new dosimeter calibration system in terms of absorbed dose to water from October 2012, too. After that, ND,w determined directly in water is delivered to radiotherapy institutions in substitution Nx. The calibration procedure by ANTM follows Standard Dosimetry 12 published by Japan Society of Medical Physics (JSMP). The concept and formalism of Standard Dosimetry are almost same to IAEA TRS 398. Ionization chambers to be calibrated are fixed at 5cm depth in water phantom. For cylindrical type chambers, appropriate waterproof sleeves are used not only to protect water but also to fix their position in the phantom. The sleeves are made of PMMA with a wall of 1mm in thickness at ionization effective volume of chamber. For flat type chambers that are water proof or have water proof cap are put into water directly.

ANTM is a calibration laboratory certified with the Japan Calibration Service System (JCSS) and can issues certificate with JCSS symbol mark. The JCSS is a standard dissemination system based on Metrological Law. The principles of JCSS are the calibration traceable to national standard and the certification of calibration laboratory. Calibration laboratories certified are proven to have sufficient technical and management competence to carry out calibration. Calibration certificate issued with JCSS symbol mark states both calibration value traceable to the national standard and its uncertainty. Users who use dosimeters calibrated can estimate the uncertainty of their own dose measurements.

During 27 months from October 2012 to December 2014, 5,193 ionization chambers were calibrated in terms of absorbed dose to water. A small differences were seen between calibration factors ND,w and Nx multiplied by kD,X for cylindrical chambers. ND,w are slightly lower than Nx·kD,X for cylindrical type. The main reason is air gap between chamber wall and water-proofing sleeve. However, there is no difference between calibration factors for flat type chambers. The reason is The standard deviation of calibration factors in consecutive two calibration using absorbed dose to water improved
SP027 - Development and Application of Phantoms in Clinical Dosimetry

**SP027.1 - Fabrication of radiotherapy phantoms using 3D printing**

**Authors:** Paul Z.Y. Liu, David R. Mckenzie, Natalka Suchowerska  
School Of Physics, University of Sydney, Camperdown/NSW/AUSTRALIA

**Aim**

3D printing is becoming more affordable and accessible. The aim of this work is to demonstrate the feasibility of using this technology to create dosimetric phantoms and customized anatomical phantoms that would otherwise be difficult to manufacture. These phantoms were designed and printed to explore the methodology, advantages and disadvantages of 3D printing techniques.

**Method**

The cylindrical dosimetric phantom, created in CAD software (Sketchup), was customized to hold an array of scintillation dosimeters to validate arc and multi-directional treatments. The anatomical phantom was created using patient CT data, which was converted into a 3D model using ImageJ. The open source software Mesh-labs was then used to prepare the model for printing.

The phantoms were printed using fused deposition with the UP 3D printer (3DPP). Both phantoms were printed as hollow objects and filled with two types of material: dental wax and gel bolus. The resulting phantoms were CT scanned to determine their density and uniformity and irradiated with a therapeutic beam to assess their suitability.

**Results**

The 3D printed phantoms are shown in Figure 1. CT scans of the printed and filled phantoms showed a uniform electron density with less than 2% variance. Gel bolus yields a uniform phantom that is close to water in mass density ($\rho_{gel} = 1.07 \text{ g cm}^{-3}$). Dosimetric characterisation of the cylindrical dosimetric phantom filled with gel bolus showed low angular dependence (<0.6%) indicating that the scintillator was located accurately on the axis.

The anatomical phantom provided an accurate surface representation of the CT image. However, the phantom density does not reflect that of the real anatomy. Other 3D printing techniques, such as selective laser sintering and stereolithography, were found to create solid phantoms of a chosen density without the need to be filled.
Figure 1. (A) The cylindrical dosimetric phantom in CAD and (B) the 3D printed phantom. (C) A CT scan of the spinal cord and (D) its printed representation.

Conclusion

The fabrication of radiotherapy phantoms using 3D printing is fast and cost effective. Fused deposition is suitable for creating dosimetric phantoms using wax or bolus to fill a hollow model. Customized patient dosimetry can be achieved with 3D printing of anatomical phantoms, however, more sophisticated printing techniques will be required to achieve the desired mass and electron densities.

SP027.2 - The effect of bismuth shielding during pediatric neck multi-detector computed tomography on thyroid dose and image quality

Author(s): Stephen Inkoom1, Antonios E. Papadakis2, Maria Rais-saki3, Kostas Perisinakis2, Cyril Schandorf4, John J. Fletcher5, John Damilakis2

Method: Four pediatric anthropomorphic phantoms that represent the average individual as newborn, 1-year-old, 5-year-old and 10-year-old child underwent routine neck computed tomography (CT) scans using a 16-slice MDCT system. Scans were performed using a) fixed tube current and b) activated-AEC technique. Each scan was performed a) without bismuth shield, b) using a single- and c) using a double-layered bismuth shield placed on the skin surface above the thyroid gland. Scans were repeated following placement of cotton spacers 1, 2 and 3 cm thick between the skin and the shield, to study the effect of skin-to-shielding distance on image noise. Thyroid dose was measured with thermoluminescent dosimeters. The location of the thyroid gland within the phantom slices was determined using a novel approach which employed 3D printed anatomical phantoms using wax or bolus to fill a hollow model. Customized patient dosimetry can be achieved with 3D printing of anatomical phantoms, however, more sophisticated printing techniques will be required to achieve the desired mass and electron densities.

Results: In fixed tube current shielded technique, thyroid dose reduction for single-layered-shield was 17% for newborn and 35% for 10-year-old, and for double-layered-shield was 25% for newborn and 47% for 10-year-old. The dose reduction for AEC-activated unshielded was 27% for newborn and 46% for 10-year-old. The corresponding reduction in AEC-activated scans for single-layered-shield was 40% for newborn and 60% for 10-year-old, and for double-layered-shield was 40 % for newborn and 66% for 10-year-old. Activation of AEC unshielded compared to fixed tube current unshielded increased the ED by 7% for 1-year-old and decreased ED by up to 27% for 5-year-old. Image noise was found to be up to 71.5, 112.5, 72.2, and 138.2 HU for fixed tube current single-layered, fixed tube current double-layered, AEC-activated single-layered and AEC-activated double-layered-shields, respectively. Elevation of shields by 1, 2 and 3 cm using cotton spacers between shields and phantoms decreased image noise, by 22.0, 9.4 and 5.5 HU respectively for fixed tube current single-layered-shield, while it did not considerably affect thyroid dose. Similar trends were observed for other protocols.

Conclusion: AEC was more effective in thyroid dose reduction compared to in-plane bismuth shields during neck MDCT. The use of fixed tube current with double-layered-shields, and AEC shielded further reduced dose; however, this is associated with higher image noise. Application of cotton spacers had no significant impact on the measured doses, but significantly decreased image noise.

SP027.3 - Use of 3D Printed Materials as Tissue-Equivalent Phantoms

Author(s): Tanya Kairn1, Tim Markwell1, Scott Crowe3

Method: This study used the example of 3D printing with acrylonitrile butadiene styrene (ABS) as a means to investigate the potential usefulness of benchtop rapid prototyping as a technique for producing patient specific phantoms for radiotherapy dosimetry. Phantom samples were evaluated in terms of their geometric accuracy, tissue equivalence and radiation hardness, when irradiated using a range of clinical radiotherapy beams.

Results: Three small cylinders and one model of a human lung (with tumour) were produced via in-house 3D printing with ABS, using 90%, 50%, 30% and 10% ABS infill densities. Physical measurements were used to test the geometric accuracy of the phantoms. Hounsfield unit values in CT scans of the sample phantoms were used to evaluate the tissue equivalence of the phantoms, in terms of densities and linear attenuation coefficients. The attenuation and scattering effects of the phantoms were also evaluated and compared with the effects of commercial tissue- and lung-equivalent plastics, using film measurements, in five different clinical electron beams and three different photon beams. The radiation sensitivity of the samples was assessed by irradiating the samples for several hours a day for 30 days and then remeasuring the densities and physical dimensions of the samples.

The measured dimensions of the small cylindrical phantoms all matched their planned dimensions, within 1mm. The lung phantom was less accurately matched to the lung geometry on which it was based; the use of manual contours to produce an initial design from the CT images led to some simplification of the shape of the lung and some conservative over-estimation of the size of the tumour.

The cylindrical 3D-printed phantoms with ABS infill densities of 30, 50 and 90% were all found to be relatively homogeneous and to exhibit densities and attenuation coefficients within the range of values identified in the commercial tissue-equivalent materials. Film measurement results confirmed that the attenuation and scattering effects of these samples were similar to the effects of established lung- and tissue-equivalent materials. By contrast, the mesh produced by the 3D printing software, when required to produce a phantom with a 10% ABS infill density was so coarse that an anatomically unrealistic structure consisting of solid ABS walls around relatively large (6 mm diameter) air chambers was clearly resolvable in the CT images of the resulting phantom.

The results of this study suggest that phantoms printed with ABS,
using infill densities of 30% or more, are potentially useful as lung- and tissue-equivalent phantoms for patient-specific radio-therapy dosimetry. A 90% ABS infill density was found to result in a material suitable for modelling tumour, muscle or other soft tissue, while ABS infill densities of 30–50% resulted in phantoms with densities low enough to model lung while also avoiding the course mesh structures that occur when lower infill densities (such as 10% ABS) are used. All cylindrical 3D printed phantom samples were found to be unaffected by prolonged radiation and to accurately match their design specifications. However, care should be taken to avoid over-simplifying anatomical structures when printing more complex phantoms.

SP027.4 - Development of water-equivalent materials using the Least Squares Method
Author(s): Leandro Mariano, Paulo R. Costa
Radiation Dosimetry And Medical Physics Group, Physics Institute, University of São Paulo, São Paulo/BRAZIL

Introduction: The study of water-equivalent materials, which have radiation attenuation and scattering properties similar to the human tissue, is central to the calculation of patient doses in many medical imaging applications. Chemical formulation using thermoplastics as a base and additives for the production of phantoms were developed by the authors for diagnostic imaging energy range (10-150keV).

Methods: The initial composition of the materials was obtained using the Hermann Method. Originally, this method allows the use of three base materials for the manufacture of the water-equivalent materials. In the present work, the Hermann’s methodology was generalized to allow the consideration of a generic number of base and additive materials. The Least Square Method was used as well to obtain the composition of the water-equivalent materials. The methodology was to fit the linear attenuation coefficient of the mixture directly on the linear attenuation coefficient of water.

Results and Discussion: The procedure developed in this work has advantages over the Hermann Method since it takes into account the linear attenuation coefficient over the entire energy range of interest. The Figure 1 shows the comparison of the linear attenuation coefficient for two formulations obtained by these methods using the same base materials.

Figure 1 – Linear attenuation coefficient of two water-equivalent materials using the Hermann and the Least Square Methods (LSM).

Moreover, the transmitted and scattered X-ray spectra of some compositions were experimentally measured and simulated using the PENELOPE code.

Conclusions: The results have shown a good agreement with the water attenuation and it has validated this methodology. The Monte Carlo Method can also be very useful to determine the characteristics of transmission and scattering of x-rays of the materials, without requiring its previous manufacture.

SP027.5 - Development of deformable moving lung phantom to simulate respiratory motion for lung SBRT
Author(s): Young Nam Kang1, Ji Na Kim2, Hyung Wook Park2, Hong Seok Jang2
1Department Of Radiation Oncology, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul/KOREA, 2Department Of Biomedical Engineering, College of Medicine, The Catholic University of Korea, Seoul/KOREA

Stereotactic body radiation therapy (SBRT) requires high accuracy in order to protect healthy organs and destroy the tumor. However, tumors located near the diaphragm are constantly moving during treatment. Respiratory-gated radiotherapy has significant potential for the improvement of the irradiation of tumor sites affected by respiratory motion, such as lung and liver tumors. To measure and minimize the effects of respiratory motion, a realistic deformable phantom is required for use as a gold standard. The purpose of this study was to develop and study the characteristics of a deformable moving lung (DML) phantom, such as simulation, tissue equivalent, and rate of deformation. The rate of change of the lung volume, target deformation, and respiratory signals were measured in this study; they were accurately measured using a realistic deformable phantom. The measured volume difference was 30%, which closely corresponds to the average difference in human respiration, and the target movement was -30 mm-+30 mm. The measured signals accurately described human respiratory signals. This DML phantom will be useful for the estimation of deformable image registration and in lung SBRT. This study shows that the developed DML phantom can exactly simulate the patient’s respiratory signal and it acts as a deformable 4D simulation of a patient’s lung with sufficient volume change.

SP027.6 - Characterization of a MOSFET-based system for skin dose evaluation with bolus material
Author(s): Anabela G. Dias1, Diana F.D.S. Pinto2
1Física Médica, Instituto Português de Oncologia do Porto Francisco Gentil, Porto/PORTUGAL, 2Radioterapia, Instituto Português de oncologia Francisco Gentil do Porto, Porto/PORTUGAL

Purpose/Objective
Post-surgery radiation therapy is one the treatment steps of locally advanced breast cancer. In vivo skin dose evaluation of the chest wall region is important to ensure sufficient dose in structures near surface and it is a valuable tool during radiation treatment to verify the delivered dose to the target. It is also useful to assess the scattered radiation to the contra-lateral breast. In certain cases, to
increase the skin dose, a bolus material with a specific thickness is frequently placed on the chest wall during the last ten treatment fractions.

The purpose of this work was to characterize a MOSFET-based system for in vivo skin measurements in megavoltage radiation (4 MV and 6 MV) and compare calculated and measured dose with and without bolus material.

**Materials/Methods**

Full characterization and calibration of the MOSFET-based system was performed regarding reproducibility, linearity, energy, angular, field size and source to surface distance (SSD) dependences for two the photons energies. All measurements with the exception of the angular dependence were performed in a solid water phantom and a Farmer ionization chamber was used for dose comparison. The angular dependence was performed with a Lucy 3D phantom from 0 to 315 degrees in 45 degree increments.

Surface dose on solid water was also assessed in the presence and absence of 1 cm bolus material and compared with calculated dose in the Treatment Planning System (TPS) (only tested with an orthogonal beam).

**Results**

The detectors presented no energy dependence and a dose linear response for the dose range studied. The measured dose standard deviation varied from 1% to 10% depending on the number of MUs (higher deviation for lower MUs) and the detector. In the therapeutic dose range, the standard deviation for all the detectors is less than 2%. The angular dependence study showed that the deviation is less than 2% over 360º. For SSD response, the system showed linear dependence. Field size dependence was also analyzed and was found to be negligible. Surface dose without bolus is about 50% less than with bolus. The comparison between the TPS calculated and measured dose with and without bolus showed a maximum difference of 5%.

**Conclusion**

Tests performed on the behavior of the measuring system in reference conditions have results consistent with the manufacturer's specifications for the studied energies. The results show that this system is suitable for in vivo skin dose dosimetry in MV range with and without using bolus material in breast external radiotherapy treatments.

**SP027.7 - Calibration procedure optimization through PSDe- signer, a multipurpose simulation platform for plastic scintillation dosimeters**

**Author(s):** Cedric Laliberte-Houdeville, Luc Beaulieu, Louis Archambault

Département De Physique, De Génie Physique Et D’optique, Université Laval, Québec/CANADA

**Background**

The literature offers a wide variety of plastic scintillation dosimeter (PSD) and multipoint PSD proof-of-concept that demonstrate how the use of plastic scintillators can lead to accurate, online and in-vivo dosimeters for radiotherapy and brachytherapy. Nevertheless this accuracy is highly dependent on the calibration procedure and the choice of calibration points (CPs). Due to the lack of clear recommendations, researchers often rely on past experiences and generally accepted consideration to calibrate their specific systems. This study presents a numerical technique to find the optimal CPs of any PSD designs. Designs inspired by the commercially available Exradin W1 and the 2- and 3-points-PSD prototypes recently published by Theriault-Proulx et al. are revis-

**Methods**

This study uses PSDesigner, a multi-purpose simulation platform written in Python to generate and evaluate virtual PSDs. With the extensive use of physical data as inputs, this platform can, among others, select optimal CPs. First, virtual PSDs are generated using emissions, attenuation and transmission spectra and response curve of commercially available optical components. Second, calibration procedure involving noisy readings as well as systematic offsets are simulated, generating flawed calibrated PSD. Finally, a stochastic algorithm searches for the best CPs resulting in the most accurate PSD.

**Results**

For the simpler, commercially available Exradin W1-design PSD, Figure 1 shows where optimal CPs ought to be selected. Both the optimal CPs and the ones suggested by Standard Imaging are shown. The latter offers a 0.4% precision on dose measurement; the former improves it down to 0.2%. Figure 1 also shows how intermediate dose to the scintillator, generated in high dose gradient regions, are to be avoided.

The same analysis can be made for a 2-points-PSD inspired system. The optimized CPs, not shown here, result in a 0.6% precision for both measurement points. Work on 3 and more points PSD system is ongoing.

**Conclusions**

The simulation platform developed validates past calibration procedures and shows its useful capabilities for future, more complex PSD design. It goes further, giving the user quantitative insight on how its procedure can be improved and how that will affect dose measurements. The code is versatile and can help researchers optimize complex PSD systems in other ways, notably through the optimal selection of optical components.
**SP028 - HIFU Therapy, Microwave Ablation, Radiofrequency Ablation, Cryotherapy**

**SP028.1 - On Understanding of the Limiting Factors in Radiofrequency Ablation on Target Tissue Necrosis Volume**

**Author(s):** Bing Zhang¹, Michael Moser², Edwin Zhang³, Yigang Luo², Wenjun Zhang⁴

¹Complex And Intelligent Systems Research Center, East China University of Science and Technology, Shanghai/CHINA, ²Surgery, University of Saskatchewan, Saskatoon/CANADA, ³Radiology And Diagnostic Imaging, University of Alberta, Saskatoon/CANADA, ⁴Biomedical Engineering, University of Saskatchewan, Saskatoon/CANADA

The aim of this study was to analyze six limiting factors that may be responsible for target tissue necrosis (TTN) generation during the process of radiofrequency ablation (RFA). A comprehensive finite element (FE) model was built to simulate TTN of a liver tissue by using a commercial available RFA system. The model was then served as a test-bed for analysis of factors. Six limiting factors were analyzed using a statistical method. Sixteen RFA experiments were performed, in which the TTN volume was considered as a response variable along with the six control factors. The TTN volumes obtained from the 16 simulations were quite different, ranging from 7.749 to 8433.931 mm³. The applied voltage (V), the frequency (f), the exposure length (L) of the RF electrode, the chilled fluid temperature (T), the large blood vessel (d) in the proximity to target tissue, and the ablation duration (t) account for approximately 78.21%, 9.93%, 2.91%, 0.01%, 4.64%, and 0.08%, respectively, of the effect on the TTN volume. The findings from the present study suggest that the applied voltage (V) and the frequency (f), followed by the large blood vessel (d) in proximity to target tissue, have the highest effect on the TTN volume.

**SP028.2 - Thermal Dose Based Monitoring of Thermal Therapy for Prostate Cancer**

**Author(s):** David Dalla Rosa¹, Hisham Assi², Joseph C. Kumaradas³

¹Apotex, Toronto/CANADA, ²Biomedical Engineering, University of Toronto, Toronto/ON/CANADA, ³Physics, Ryerson University, ON/ CANADA

Thermal dose is a metric for quantifying the amount of thermal damage taking temperature and exposure time into account. An ideal thermal dose model should produce the same dose for a given amount of damage, regardless of the heating protocol used, or the time-temperature profile that caused the damage. The cumulative-equivalent-minutes at 43 Celsius (CEM43) is the most commonly used thermal dose model. It was originally developed for hyperthermia applications (less than 45 Celsius). The validity and accuracy of this mode for higher temperatures, above 50 Celsius is questionable. A new thermal dose model based on the Arrhenius type Vogel-Tammann-Fulcher equation, known as the improved cumulative equivalent minutes at 43 Celsius (iCEM43), has been developed and fit to publish historic thermal data.

The CEM43 and iCEM43 dose models have been retrospectively used to assess the dose delivered to during laser thermal therapy of low-grade prostate cancer, in order to test the consistency of the two methods. This was done by obtaining MRI thermometry images during treatment and gadolinium enhanced MRI images post-treatment to assess vascular shutdown (as an indicator of acute thermal damage), as shown in the figure below. The iCEM43 dose model was found to be more consistent than the CEM43 dose model in predicting post-treatment vascular shutdown.

**SP028.3 - Nanodrug Delivery and Anti-tumor Efficacy for Brain Metastasis of Breast Cancer Enhanced by Short-time Low-dose Ultrasound Hyperthermia**

**Author(s):** Sheng-Kai Wu¹, Chi-Feng Chiang⁴, Yu-Hone Hsu¹, Tzu-Hung Lin², Houngh-Chi Liou³, Wen-Mei Fu², Win-Li Lin³

¹National Taiwan University, Institute of Biomedical Engineering, Taipei/TAIWAN, ²National Taiwan University, Institute of Pharmacology, Taipei/TAIWAN, ³National Health Research Institutes, Institute of Biomedical Engineering and Nanomedicine, Miaoli/TAIWAN

Ultrasound hyperthermia can enhance the delivery of chemotherapeutic agents into tumors, while the blood–brain/tumor barrier inhibits the uptake and accumulation of chemotherapeutic nanodrugs in brain tumors. In this study, we investigated the effects of short-time low-dose (STLD) focused ultrasound (FUS) hyperthermia on the delivery and therapeutic efficacy of pegylated liposomal doxorubicin (PLD) for brain metastasis of breast cancer. Murine breast cancer 4T1-luc2 cells expressing firefly luciferase were injected into female BALB/c mice striatum tissues and used as a brain metastasis model. The mice were intravenously injected with PLD with/without STLD transcranial pulsed/continuous wave FUS hyperthermia on day 6 after tumor implantation. The amounts of doxorubicin accumulated in the normal brain tissues and tumor tissues with/without FUS hyperthermia were measured using fluorometry. The tumor growth for the control, hyperthermia, PLD, and PLD+hyperthermia groups was measured using an IVIS spectrum system every other day starting from day 3. Cell apoptosis and tumor characteristics were assessed using immunohistochemistry. The experimental results showed that STLD transcranial FUS hyperthermia was able to significantly enhance the PLD delivery into brain tumors. The tumor growth was effectively inhibited by a single treatment of PLD+hyperthermia compared with both PLD alone and STLD FUS hyperthermia alone. Immunohistochemical examination further demonstrated the therapeutic efficacy of PLD plus STLD FUS hyperthermia for brain metastasis of breast cancer. The results also showed that with the same STLD, pulsed-wave can even produce a better therapeutic result than continuous-wave FUS hyperthermia. This study indicates that the application of STLD FUS hyperthermia after nanodrug injection may be an effective approach to enhance nanodrug delivery and improve the treatment of metastatic cancers.
A critical goal in breast conservation surgery (BCS) is to obtain negative surgical margins to ensure removal of all cancerous tissue. This process usually requires a period of several days to evaluate margin status with conventional pathology, and results in re-excisions for 20-60% of BCS patients due to the lack of a rapid, noninvasive method to evaluate margins in the operating room. Several methods are therefore being investigated for the intraoperative evaluation of margin status. High-frequency (HF) ultrasound (20–80 MHz) was investigated in a 17-patient pilot study for intraoperative margin evaluations during BCS. Through-transmission measurements were acquired from 53 positions on 34 excised specimens at the Huntsman Cancer Institute, Salt Lake City, Utah. Specimens included lymph nodes, surgical margins, tumors, and fibroadenomas. Measurements were acquired with the use of two 50-MHz immersion transducers (Olympus NDT, V358-SU), a HF square-wave pulser/receiver (UTEX, UT340), and a 500-MHz digital oscilloscope (Hewlett-Packard, HP-54522A). Ultrasonic waveforms were averaged in the signal acquisition and downloaded onto a notebook PC using LabVIEW. Parameters acquired from the data included peak density (the number of peaks and valleys in the 20-80 MHz band of the ultrasonic spectra) and attenuation. Peak density is strongly dependent on scattering processes and thus microstructural heterogeneity in the tissue. Statistical analysis of the data for differentiating between malignant and nonmalignant tissue revealed that peak density and attenuation by themselves provided lower accuracy and sensitivity as compared to a multivariate analysis combining the two parameters. Results from the multivariate analysis showed 81.1% accuracy, 76.9% sensitivity, and 85.2% specificity. Table 1 compares the accuracy, sensitivity, and specificity values of HF ultrasound with alternative technologies for intraoperative BCS margin assessments, and shows HF ultrasound is competitive with both small specimen mammography and radio-frequency spectroscopy. Approaches for improving the HF ultrasound method include using additional parameters in the multivariate analysis such as wave speed, calibrating the measurements with phantoms, and conducting larger studies with statistically relevant numbers of patients, specimens, and measurement positions. Such a study at the Huntsman Cancer Institute is currently near completion, and includes 73 patients, 485 specimens, and 1112 measurement positions. Preliminary results are consistent with those from this study.

**Table 1.** Comparison of results from prospective and clinical trials of margin evaluation methods including small-specimen mammography, radio-frequency spectroscopy, and high-frequency ultrasound.

Breast cancer is the second most prevalent cancer among women, affecting one out of eight in their lifetime. The ability to differentiate between malignant and normal tissues during breast cancer surgery would enable the surgeon to remove all of the cancer from the affected region in the breast, thereby reducing the risk of recurrence and the need for subsequent surgeries. Two studies conducted at the Huntsman Cancer Institute (Salt Lake City, Utah) showed that high-frequency (HF) ultrasound (20–80 MHz), and in particular the ultrasound parameters peak density and attenuation, were sensitive to breast tissue pathology. The objective of this study was to determine the effect of tissue microstructure on peak density and attenuation using phantoms that mimic the histology of breast tissue. Phantoms were created from a mixture of distilled water, agarose powder, and 10X TBE stock solution. In order to simulate breast tissue histology and breast density, polyethylene microspheres were embedded into the phantoms in layers, totaling 4 layers per phantom. In one experiment, the volume percent of polyethylene microspheres was kept constant in each phantom while varying microsphere sizes (58–925 μm diameter). In a second experiment, the polyethylene microsphere size (90–106 μm diameter) was kept constant within each phantom while the weight percent concentration of the microspheres varied (0.00g to 0.06g). Pitch-catch measurements were acquired using 50-MHz transducers (Olympus NDT, V358-SU, 0.635-cm diameter active element), a HF pulser-receiver (UTEX, UT340), and a 1-GHz digital oscilloscope (Agilent, DSOX3104A). Glycerol (Genesis Scientific) was used as a coupling agent between the transducers and the phantoms. Spectra were derived from the data, giving peak density (the number of peaks and valleys in the 20–80 MHz range) and attenuation values. The results show that peak density is much more sensitive to the size of the heterogeneity and follows an inverse size (microsphere diameter) relationship, while attenuation is sensitive to the number of heterogeneities present. These results demonstrate that the HF ultrasound parameters, peak density and attenuation, are sensitive to changes in microstructure or heterogeneity observed in malignant breast tissue. Clinical breast cancer studies also showed that, when combined in a multivariate analysis, peak density and attenuation increased the accuracy, specificity, and sensitivity of the measurements for malignant tissue. The high-frequency ultrasound results from the agarose phantoms confirm that peak density and attenuation are complementary parameters for characterizing breast tissue pathology and validate the clinical breast cancer studies conducted at the Huntsman Cancer Institute.
SP028.6 - Rapid Molecular Subtyping of Breast Cancer Using High-Frequency Ultrasound (10-120 MHz) and Principal Component Analysis

**Author(s):** Caitlin Carter1, Laurel A. Thompson2, Amy Fairbrother1, Timothy E. Doyle1

1Biology, Utah Valley University, Orem/UT/UNITED STATES OF AMERICA, 2Chemistry, Utah Valley University, Orem/UT/UNITED STATES OF AMERICA

**Introduction:** The molecular subtypes of breast cancer correlate more strongly to prognosis and treatment response than traditional classifications based on genetic and protein expression profiles. The mutations found in aggressive subtypes (basal-like and Her2+) alter the expression levels of proteins that regulate the actin cytoskeleton, thereby altering the biomechanical and ultrasonic properties of the cell. Current methods of testing these changes do not easily transfer to real-time diagnostic methods. The ability to determine the subtype of breast tumors during surgery or biopsy would provide physicians with new diagnostic capabilities to screen suspicious lesions, as well as perform high-precision surgery and personalize treatment for patients.

**Objective:** The hypothesis of this work was to determine the feasibility of using high-frequency ultrasound and principal component analysis (PCA) to characterize and phenotype different molecular subtypes of breast cancer cell lines, and to determine the sensitivity of high-frequency ultrasound to changes in biomechanical properties of the cell.

**Methods:** Computer simulations were performed to determine if changes in the bulk and shear moduli of the cell cytoplasm would measurably alter high-frequency ultrasonic spectra. To verify these models, ultrasonic measurements of seven breast cancer cell lines with different molecular subtypes were obtained over a period of two years by taking pulse-echo measurements of the cell layer with a 50-MHz transducer immersed directly in the growth media of the cell culture plates. The cell reflections within the waveforms were isolated and spectrally analyzed using computer models and PCA. Heat maps were then generated using relative distances between PCA scores of experimental data and model spectra. These heat maps were used to classify the spectra for subtype profiling. A secondary experiment was performed to validate that the cell reflections isolated from spectral data were in fact the waveforms of the cellular monolayer signal, and to determine if chemical modification of the cytoskeleton could be observed with ultrasound. This was done by treating a cell culture with colchicine which is a known inhibitor of cytoplasmic microtubule formation. Measurements of the treated culture were taken incrementally over a period of 90 minutes to record the effect on the cell signal in real time.

**Results:** Computer models showed that changes in biomechanical properties of the cell cytoplasm would significantly alter the cell's ultrasonic properties. Experimental results showed that each cell line produced a unique spectral signature while also demonstrating changes due to seeding density. This showed the sensitivity of high-frequency ultrasound to changes in cell microenvironment as well as the molecular subtype of the cells. The colchicine data also verified changes in the cell signal due to the modification of cytoplasmic microtubules. The heat map generated from PCA was able to classify the measured spectra of each cell line based on their individual biomechanical and morphological properties.

**Conclusions:** The experimental and computational results of this work have demonstrated that high-frequency ultrasound is a feasible method for rapid molecular subtyping of breast cancer. Principal component analysis of the spectral data has additionally demonstrated a prospective approach for the characterization of molecular subtypes.

SP028.7 - Inverse treatment planning using radiofrequency ablation in cancer therapy

**Author(s):** Shefali Kulkarni-Thaker1, Dionne Aleman1, Aaron Fenster2

1Department Of Mechanical And Industrial Engineering, University of Toronto, Toronto/CANADA, 2Imaging Research Laboratories, Robarts Research Institute, London/CANADA

Radiofrequency ablation (RFA) offers localized and minimally invasive ablation of small-to-medium sized inoperable tumors. In RFA, tissue is ablated due to high temperatures obtained from the current passed through electrodes inserted percutaneously or via open surgery into the target. However RFA can cause incomplete ablation due to several reasons including incorrect needle position. We develop a mathematical framework for pre-operative inverse treatment plans for single and multiple RFA applicators. Borrowing techniques from radiosurgery inverse planning, we design a two stage algorithm where we first identify needle position and orientation, referred to as needle orientation optimization, and then compute the treatment time for optimal thermal dose delivery using thermal dose optimization (TDO). We develop linearly-relaxed TDO models using various thermal damage models including threshold temperature using Pennes Bioheat transfer equation (BHTE) and Arrhenius damage index. We present experimental results on three clinical case studies with 3D patient models.
SP029 - Surgical Navigation: Part 1

SP029.1 - Preliminary evaluation of positron emission based 3D tracking system (PeTrack) in image guided interventions

**Author(s):** Simin Razavi1, Benjamin Spencer2, Marc Chamberland3, Tong Xu2

1Department Of Physics, Carleton University, Ottawa/CANADA, 2TIMC-IMAG Laboratory, La Tronche cedex/FRANCE, 3Department Of Physics, Carleton University, Ottawa/ON/CANADA

In minimally invasive surgeries, a surgeon needs to precisely locate the surgical tools. The recent advancements in image guided surgeries have enabled monitoring the position of the operative tools in the vicinity of internal organs. We are developing a new real-time three-dimensional (3D) tracking technique for medical procedures called PeTrack (Positron Emission Tracking). PeTrack is designed to track the location of a positron emitting fiducial marker(s) using two pairs of position sensitive gamma ray detectors. The marker can be attached to surgical instruments (e.g. a catheter). PeTrack provides the location of the marker in real-time. PeTrack is co-registered with an x-ray C-arm to enable the navigation (Figure 1).

**Figure 1**

The emitted positron from fiducial marker annihilates with an electron, producing two gamma rays in opposite directions. Gamma rays which belong to single annihilation create coincidence line (COIL). The true location of PeTrack marker is defined to have the minimum root mean square distance to all of the COILs collected in a short time interval (e.g. 100 ms). We studied the sensitivity and distortion of PeTrack by Monte-Carlo simulations and experiments. Results show that the sensitivity fluctuates within the detector field of view and revealed a non-uniform distortion. The distortion can be reduced less than 1 mm by correcting for systematic errors. We also performed a navigation experiment by moving a 13.5 μCi marker along a simulated blood vessel and co-registered its positions with an x-ray projection image. Figure 2 shows that PeTrack correctly tracked the locations of the marker.

**Figure 2**

The small dose from the PeTrack marker is offset by the dose reduction when using PeTrack for tracking instead of continuous x-ray fluoroscopy. Therefore, as a wireless tracking technique with sub-millimeter marker and sub-millimeter accuracy, PeTrack has a great potential for 3D navigation during image guided surgery.

SP029.2 - Seymour Shield – An Operative Adjunct Device for Maintaining Visualization during Laparoscopic Surgery

**Author(s):** Kartik Kannan1, Foad Kabinejad2, Leo Hwa Liang1, Justin Phoon1, Perline Teo1, Ng T. Kiat2, Luke Tay2

1Bio-engineering Department, National University of Singapore, Singapore/SINGAPORE, 2Department Of Surgery, National University of Singapore, Singapore/SINGAPORE, 3QiG Group, singapore/SINGAPORE, 4A*STAR, singapore/SINGAPORE, 5Senior Consultant, Urology, National University Hospital, singapore/SINGAPORE, 6General Surgery, Singapore General Hospital, singapore/SINGAPORE

During Minimally Invasive Surgery or Laparoscopic Surgery, the surgeon is absolutely dependent on the view from the camera. Yet, the rigid-endoscopic camera lens is prone to getting fouled by smoke, fog, blood and/or vaporized organic debris, all of which obstruct vision and thus necessitates removal of scope from abdomen for cleaning. So when lens fouling happens, surgical workflow halts entirely, which jeopardized patient’s safety when visualization is truncated. Hence the scope is removed and the lens is manually cleaned by the nurse with the help of the gauze. Lens is warmed frequently by submerging the tip into a thermos-flask filled with warmed water and it is dried to prevent fogging. Surgeon must then return camera to its previous location and spatially re-ordinate himself in order to resume work. Disruptions in workflow may lead to conversion to open surgery for emergency measures, especially during active bleeding. Currently, conversion rate stands at 10% for most of the laparoscopic surgeries. Time lost contributes to operative duration, which is an independent risk factor for morbidity, as well as cost to the healthcare system. Given that 3.1 million laparoscopic surgeries were performed in USA in 2012 (projected to grow at 5-8%), we estimate a total of 386,000 hours spent cleaning the scope, representing wastage of USD 347 Million in terms of theater time to healthcare system.

At present, laparoscopic sheaths have been devised with fluid irrigation channels that enable lens cleaning without scope removal (EndoScrub 2, Medtronic). However, this still involves loss in visualization and disruption of surgical flow while irrigation is taking place. Recently, a sheath generating air vortex distal to the lens has been developed which disperses smoke produced during electro-cautery dissection (Flosheild, MID Surgical). However it is not effective against blood splatter and thus fails to protect the lens during the most critical moments of the surgery.

Hence, to overcome the above defects, we developed a novel
device, the one-stop solution which addresses all the problems encountered. Our product Seymour Shield is a 12mm/14mm sheath that fits over the conventional 10 mm laparoscopic camera with a distal, constantly-rotating, clear, transparent disc (shield). The rotation serves two purposes; firstly, to remove or prevent buildup of excess fluid and particulate debris on the visualization surface by centrifugal force, and secondly to produce an optical illusion of clarity exploiting physiological persistence of vision and the flicker-fusion threshold of human sight. We are using compressed air\n vacuum which is available readily in Operation Theater as a driver for the whole process. Rotor is designed in such a way that it is propelled by the compressed air and the transparent disk or the shield for the lens is embedded into the rotor. So, as the rotor rotates at high speed, the shield too rotates, thereby shattering all the foreign particles. The compressed air can be used by the doctor whenever required, by just pressing the button in the sheath. Thus Seymour Shield offers easy and instant solution for maintaining clear vision throughout the laparoscopic surgery.

Fig. 1: The upper bound of tumour volume such that there is <95% probability of obtaining a sample with ≥50% core involvement, given needle delivery error of the biopsy system.

Impact:
Optimized planning of within-tumour targets for fusion biopsy could support earlier diagnosis of prostate cancer while it remains localized and curable.

SP029.3 - Optimizing MRI-targeted fusion prostate biopsy: the effect of systematic error and anisotropy on tumour sampling

Author(s): Peter Martin1, Derek W. Cool2, Cesare Romagnoli2, Aaron Fenster1, Aaron D. Ward3
1Medical Biophysics, Western University, London/ON/CANADA, 2Medical Imaging, Western University, London/CANADA, 3Oncology, Western University, London/ON/CANADA

Purpose:
Random, systematic and anisotropic biopsy needle delivery errors can arise due to patient and prostate motion, image registration errors, and device-to-image calibration issues. The purpose of this work was to investigate the effect of needle delivery error on tumour sampling probabilities, as a first step toward our over-arching aim of optimizing needle target positions within tumours, accounting for guidance system errors, image registration errors, and irregular tumour shapes.

Methods:
We obtained multiparametric MRI and 3D TRUS images from 49 patients. A radiologist and radiology resident contoured 81 suspicious regions, yielding tumour surfaces that were registered to the TRUS images using an iterative closest point prostate surface-based method. The probability of obtaining a sample of tumour tissue in one attempt was calculated by integrating a 3D Gaussian distribution over each tumour domain, where σ = the needle delivery error. One attempt was calculated by integrating a 3D Gaussian distribution over each tumour domain, where σ = the needle delivery error. The probability of obtaining a sample of tumour tissue in one attempt was calculated by integrating a 3D Gaussian distribution over each tumour domain, where σ = the needle delivery error.

Results:
Our experiments indicated that a biopsy system’s lateral and elevational errors have a much greater effect on sampling probabilities, relative to axial error. We have also determined that systematic errors with magnitude <2 mm have a relatively small incremental effect on sampling probabilities. For a fusion biopsy system with a typical needle delivery error of 3.5 mm, tumours of volume ≤1.9 cm³ may require more than one biopsy attempt to ensure 95% probability of a sample with 50% core involvement, and tumours ≤1.0 cm³ may require more than two attempts (Figure 1).

SP029.4 - Is hemolysis influenced by the dynamic calibration method of CPB roller pumps?

Author(s): Francisco U. Vieira Junior1, Nilson Antunes2, Eduardo T. Costa2
1Federal Institute of São Paulo, Campinas/BRAZIL, 2Cardiac, Campinas State University, Campinas/BRAZIL, 3Biomedical Engineering, Campinas State University, Campinas/BRAZIL

Introduction: Roller pumps are widely used in cardiopulmonary bypass (CPB) surgeries due to the ease of their operation, maintenance, safety and cost. Several studies have compared the use of roller pumps with centrifugal pumps but few have evaluate the influence of the different roller pump adjusts on hemolysis. The objective of this work was the in vivo analysis of the influence of roller pump adjustment by the dynamic method on hemolysis prevention.

Methodology: We have measured the hemolysis rate of 87 patients submitted to myocardial revascularization, divided in 4 groups, altering the roller pumps adjustment by the dynamic method. We have used an Auxiliary Calibration Device specially developed for this purpose. The adjustments consisted in the monitoring of the pump output pressure (pump at 10 rpm) with the output tube pinched, the pump rollers were adjusted in order to have mean pressures between 75 and 450 mmHg. The adjustment for each group was as follows: Group 1 (n=20) - 75 mmHg; Group 2 (n=24) – 150 mmHg; Group 3 (n=22) – 300 mmHg; and Group 4 (n=21) – 450 mmHg. The hemolysis rates were measured before the start of CPB (T0) and 5 minutes after CPB (T1). The blood plasma free hemoglobin (HLP) was calculated using a spectrophotometer and the data related to a measurement at instant “t” was corrected for the hemodilution according to the equation below using Htbase = 27.5%:

\[ HP(t) = HLP(t) \times Htbase / Ht(t) \]
The hemolysis rates (Tx) were calculated for each patient for the interval T0-T1 using the following equation:

\[ Tx = \frac{(HLp1 - HLp0)}{(T1 - T0)} \]

**Results:** In Table 1 we show the measurement results for each group. Our results have not shown statistical difference for hemolysis rates between groups (p>0.05).

Table 1 – Registered times during CPB with respective measures of free hemoglobin and hemolysis rates. Values are mean ± standard deviation.

* Comparison between groups.

**Conclusion:** Our results have shown that the calibration of the roller pumps for different adjustments have not influenced the hemolysis rates in the analysed groups. Little occlusive calibrations should be avoided due to possible reflux and errors in flow measurements based on the pump rotation.

**SP029.5 - A Fiducial Apparatus for 6DOF Pose Estimation of an External Echo Probe from a Single X-ray Projection: Initial Simulation Studies on Design Requirements**

**Author(s):** Charles R. Hatt1, Amish N. Raval2, Michael A. Speidel3

1Medical Physics, University of Wisconsin, Madison/UNITED STATES OF AMERICA, 2Cardiovascular Medicine, University of Wisconsin, Madison/WI/UNITED STATES OF AMERICA, 3Medical Physics, University of Wisconsin, Madison/WI/UNITED STATES OF AMERICA

X-ray fluoroscopy (XRF) is considered the primary imaging modality for guidance during cardiac interventions. However, visualization of soft tissue is limited. Image registration between transthoracic echocardiography (TTE) and XRF could potentially be used to fuse soft-tissue imaging with device imaging in minimally sedated patients. We propose a method of XRF/TTE image registration in which a fiducial apparatus is rigidly attached to the TTE probe, and the 3D pose of the fiducial is determined based on its appearance in the XRF image. The fiducial consists of a constellation of radio-opaque markers with known geometry. 3D pose estimation accuracy depends on 1) accurate marker localization in the XRF image, 2) geometric properties of the apparatus such as marker diameter, overall apparatus dimensions, marker count, manufacturing tolerances, and 3) pose estimation method. In this work, we performed simulation studies to examine the effect that each variable had on the 3D target registration error (TRE). In the first experiment, we generated simulated XRF images of a spherical marker with varying levels of peak signal-difference-to-noise ratio (pSDNR) and varying marker diameters, and measured the effect on marker localization error (MLE). In the second experiment, using a circular constellation of markers, we tested the effect that MLE, manufacturing tolerance, apparatus dimensions, marker count, and shape constraints during optimization had on TRE. Our results showed that MLE was roughly 0.14, 0.05, 0.02 mm for pSDNRs of 10, 20 and 30 using a 2 mm diameter spherical marker. TRE decreased as the marker count and apparatus diameter increased. Manufacturing error increased TRE, but had minor effects for clinically relevant levels of MLE. Results indicate that, for a “medium” level of pSDNR (~15), the optimal fiducial configuration can achieve a 3DTRE of 0.32 ± 0.22 mm, and can achieve a 3DTRE of less than 1.5 mm for noisier images.

**SP029.6 - Mechanism design a flexible endoscope with USB adaptation to training.**

**Author(s):** Francisco D. Perez Reynoso1, Daniel Lorias Espinoza2, Rigoberto Martínez Méndez2

1Ingeniería Electrica, Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional, Distrito Federal/MEXICO, 2Ingeniería Electrica, Universidad Autónoma del Estado de México, Toluca México/MEXICO

The aim of this paper is to present a mechanism to adapt a boroscopic camera to the operation of a flexible endoscope and get the vision of a real device, leveraging technology for portable devices to provide surgeons the visualization so important in the training and application of endoscopy, because without this tool is virtually unenforceable.
SP030 - Lab-on-chip, BioMEMS and Microfluidics

TRACK 08: BIOSENSOR, NANOTECHNOLOGY, BIOMEMS AND BIOPHOTONICS

SP030.1 - Drop-based microfluidics for diagnostic applications
Author(s):
This talk will introduce the use of microfluidics to control very small aqueous drops that can be used as microreactors to perform millions of experiments in very short times and using very small quantities of reagents. These systems have great potential for use in many research and diagnostic applications. Some of these will be described.

SP030.2 - Enhanced multielectrode configurations in miniaturized 3D electrical impedance spectroscopy and tomography - monitoring the overall process of tissue engineering with spatial sensing for future challenges in microfluidics
Author(s):
Over the past two decades, 3D cell culture models have attracted considerable attention to achieve, e.g., in vivo-like structural organization, gene and protein expression, response to stimuli, drug metabolism. A significant challenge in this regard is gaining spatially distributed information when monitoring cell proliferation on a biocompatible scaffold displaying well defined physico-chemical properties. Electrical impedance spectroscopy (EIS) has been shown to be a non-invasive method for biomaterial characterization and monitoring microfluidic cell cultures, gaining an insight on cellular activity and proliferation over time.

We have developed and validated planar and needle-based multielectrode systems which offer the advantage of switching among different two-, three- and four-electrode configurations to focus impedance-based sensing on specific sub-volumes in a 3D cell culture. Information about scaffold architecture supporting cell organization (e.g. porosity, Fig. 1A), medium conductivity, and 3D spatial distribution of cells can be obtained. Furthermore, four-electrode configurations can also be used for electrical impedance tomography (EIT)-based imaging to map the conductivity distribution within a miniaturized 3D cell culture system (Fig. 1B). Finite element simulations were used to optimize electrode number, spacing and orientation with respect to the bioreactor geometry by maximizing the derived sensitivity field distribution for measurements. Validation with phantom experiments, mimicking cell clusters (Fig. 1C), and cell-based experiments was performed aiming to incorporate spatially enhanced 3D sensing into a 8-channel bioreactor array with integrated microfluidics for real-time monitoring of cell proliferation in porous scaffolds (Fig. 1D). The integration of the developed non-invasive sensing methods enable monitoring of tissue development within otherwise inaccessible areas of a 3D tissue construct, overcoming limitations of more traditional optical techniques.
A) Comparison of scaffold porosity between standard method (weight-based) and EIS-based method for different pore densities.

B) Example of EIS-based scaffold porosity mapping.

C) Multiplexing mode 1 results showing impedance (ZL) vs. frequency for different phantoms.

D) Bioreactor setup with inlets, outlets, electrodes, and Lego® motor control.
In 3D environment there is a need for adding the third dimension to EIS sensing for spatial resolution to gain information about distribution of cells in the scaffold (Fig. 1Ba,b,c). Moreover, electrode number, geometry and orientation need to be optimized with respect to the deriving sensitivity field distribution. In order to gain information with a good resolution, we show that several two-, three- and four-electrode measurements can be combined to create complementary sensitivity fields which individually focus on specific volumes inside the 3D cell culture and, taken together, cover the whole measurement chamber volume. This approach was tested for growing hepatoblastoma (HepG2) cells embedded within a 5% w/v gelatin scaffold (Fig. 1Bd).

Electrochemical impedance spectroscopy (EIS) has been proved to be a valuable technique for label-free, real-time and minimal invasive detection of cellular functions in fundamental and applied research. During the last three decades, several two-dimensional (2D) impedance-based systems have been widely used for studying cell adhesion and spreading, proliferation and death. Nowadays, there is an increasing interest towards three-dimensional (3D) cell cultures, which are proposed to create and maintain a more in vivo-like environment. EIS can be applied at different stages when developing a 2D or 3D culture setup, starting from bare scaffold and electrode characterization to monitor cell proliferation and tissue functionality. We present theoretical and experimental comparison of several electrode configurations (or modes) both in 2D (Fig. 1A) and 3D (Fig. 1B) used for following cell growth in real-time. Two different 2D modes were explored measuring between: i) the two combs (working electrode a vs b, WEa vs WEB), interdigitated configuration (Fig. 1Aa,b,c) and ii) WE versus a large counter electrode (CE), conventional “vertical” configuration, and found that the interdigitated configuration provides a higher sensitivity when monitoring HeLa cells adhesion, spreading and growth over 24-h (Fig. 1Ad).
SP030.4 - Development of Microfluidic Paper-Based Electrochemical Immunoassays for the Detection of Prostate Cancer

Author(s): Sean P. Rawlinson, Prosper Kanyong, James McLaughlin, James Davis

Nibec, School Of Engineering, University of Ulster, Newtownabbey/UNITED KINGDOM

Prostate cancer or carcinoma of the prostate is one of the most frequently diagnosed malignancies in the world. Prostate cancer is the second leading cause of cancer death in men worldwide and the fourth most common cancer overall, with more than 1.1 million new cases diagnosed in 2012, and more than 307,000 deaths from the disease. The prevalence of the condition and mortality will clearly vary from one country to another but tends to be higher in developed countries. Prostate cancer incidence is strongly linked to age with the lowest incidence rates being in younger men. In the UK between 2009 and 2011, only 1% of cases were diagnosed in men under 50 and an average of 36% of cases was diagnosed in men aged 75 years and over. In a population with increasing longevity, it is likely that prostate cancer will become even more clinically prevalent in the future. This projected increase is a major concern for the public health sector, especially when there are both problems associated with the detection and the treatment of prostate cancer. Specifically, current practice in prostate cancer and staging leads to inaccurate assessments often resulting in unwanted or even unnecessary treatments that adversely affect the patient’s quality of life with little gain. It will also place a considerable burden on the healthcare provider.

The poster presentation details a new approach to the development of microfluidic paper-based electrochemical devices that will be capable of multiparametric detection. Rather than examining single parameter detection, the strategy adopted here involves the laser machining of cellulose based substrates to create an array of microfluidic channels and detection wells as detailed in Figure 1. Screen printed electrodes are positioned within the wells and can be functionlised with a variety of molecular recognition elements (enzyme or antibody) thereby providing a system which is capable of screening a panel of biomarkers relevant to the diagnosis of prostate cancer. The design, development and bioanalytical characterisation of the prototype sensing systems will be presented and the applicability to point of care diagnosis critically assessed.

Figure 1. Schematic of the microfluidic array.

SP030.5 - Investigating chip design for a Raman microfluidic system with clinical radiobiological applications.

Author(s): Samantha J. Harder1, Julian J. Lum2, Andrew Jirasek3, Alexandre G. Brolo4

1Physics And Astronomy, University of Victoria, Victoria/CANADA, 2Deelely Research Centre, BC Cancer Agency, Victoria/BC/CANADA, 3Physics, University of British Columbia - Okanagan, Kelowna/BC/CANADA, 4Chemistry, University of Victoria, Victoria/BC/CANADA

Raman spectroscopy (RS) has been demonstrated as valuable for studying biomolecular responses of human cancer cells to clinically relevant doses of ionizing radiation.1 Radioresistance in cancer therapy remains a significant problem and recent studies indicate that RS may provide important biological insight into mechanisms of radioresistance.2 Raman microfluidic (RMF) systems offer several potential advantages over traditional single cell Raman data acquisition techniques. The precise control of suspended particles in microfluidic environments facilitate automation of data collection, reducing the time required and user dependence of data acquisition. RMF systems facilitate efficient sample use which is favourable when dealing with small or rare samples- as is the case with patient biopsies. RMF systems have the potential to make RS more accessible for applications in the clinic and for wide-spread radiobiological studies. The objective of this work is to investigate microfluidic chip design for single cell Raman spectroscopic studies in radiobiology.

Three different prototype RMF systems have been investigated, to determine an optimal chip substrate and design. The first system is formed from polydimethylsiloxane (PDMS) using soft lithography techniques.3 This system varied slightly from traditional PDMS microfluidic systems by employing a MgF2 coverslip to seal the system instead of glass. MgF2 exhibits a relatively weak Raman spectrum in the spectral region of interest, compared to most glasses, making it ideal as a substrate material for chip design. Second, a novel RMF design was realized by forming the base and top surfaces of the chip using MgF2 with Paraflim forming the channel walls. Lastly, a novel design made entirely out of MgF2 was tested. A channel was laser etched into MgF2 using a Ti:Sapphire laser, and the system was sealed using a MgF2 coverslip. Raman spectra from single cells in each RMF system have been collected, using a Renishaw inVia Raman microscope coupled with a 785 nm laser, in order to determine the optimal chip design for radiobiological Raman studies.

The PDMS based RMF chip yielded cell spectra which were contaminated by Raman peaks characteristic of PDMS. These peaks interfere with cellular Raman signals in spectral regions which are important for assessing radiation-induced responses in cells.4 The PDMS chip design is, therefore, unsuitable for radiobiological applications. The novel Paraflim-MgF2 and solid MgF2 chip designs yielded suitable cell spectra for studying radiation-induced biomolecular changes in cells, since in both cases there were minimal contributions from the chip material in the Raman spectra.

Both the novel Paraflim-MgF2 and solid MgF2 chip designs are promising for single cell Raman radiobiological studies. Both systems warrant further investigation as potential designs which may facilitate adaptation of Raman spectroscopy for the clinic and for wide-scale biological research.

Biological investigations during acute and/or long-term hypoxia have become an important key in research that requires extraordinary experimental design. We present a platform of a multifunctional lab-on-a-chip (LOC) system for hypoxic investigation on biological single cells with controlled oxygen content and surroundings. The LOC was combined with the patch clamp technique for electrophysiological investigations, optical tweezers for manipulation of the individual cells in 3D within the closed micro-channel system, absorption spectroscopy to monitor and acquire the spectral response of the cells to different oxygenated states and oxygen sensor to monitor the oxygen level within the chip. All techniques was built on the optically table (Figure 1A). The developed gastight LOC in Plexiglas monitored the oxygen level within the chip. All techniques was an inverted microscope (IX71, Olympus, Japan), on a vibration free optical table (Figure 1A). The developed gastight LOC in Plexiglas with an integrated patch-clamp micropipette (Figure 1B) is aimed to replace the open system in conventional patch clamp technique to achieve control of the gaseous surroundings of the investigated cells. To test the system, a single red blood cell (RBC) from Chicken (Fitzgerald Industries International, USA) was trapped optically, moved in 3D through the micro-channels of the chip towards the integrated micropipette within the gastight chip. The oxygen levels dissolved in the extracellular solution within the micro-channels was monitored by an oxygen sensor (FOXY, AL3000, Ocean Optics, USA) reached values between 0-18% O2 which was verified by studying the oxygenation states of the trapped RBC with UV-Vis absorption spectra (Ocean Optics, HR4000, USA) simultaneously, (Figure 1C). The spectral transfer of the investigated cell from the oxygenated state (18% O2) to the deoxygenated state (0% O2) happened after about 3.7 minutes while a fully developed deoxygenated spectrum was observed after 4.9 minutes. The gas tightness of the hypoxic chamber to the oxygen diffusion was verified by stopping the flow of deoxygenated solution into the channel system while continuously recording UV-Vis spectra, showing an unchanged deoxygenated state during 90 min. Thereafter, a transfer to the oxygenated absorption spectra was achieved after 7.1 minutes when exposing the cell to normoxic buffer solution. The result above showed the long time viability of the investigated cells as well as the control of the hypoxic conditions within the chip. To verify the system for physiological investigations, successful patch clamp investigations (EPC-7, HEKA, Germany) on a trapped RBC were established and the whole-cell access (Ra) and membrane resistances (Rm) were measured to be 5.1 MΩ and 900 MΩ respectively.

Figure 1: A. Schematic figure of LOC system including all technique. B. LOC system integrated with patch clamp technique. C. Absorption spectra of optically trapped chicken RBC with measured oxygen levels and time scale.
SP031 - Pattern Classification

TRACK 09: BIOSIGNAL PROCESSING

SP031.1 - The Recognition of Pinch-to-Zoom Gesture Based on Surface EMG

**Author(s):** Jongin Kim1, Dongrae Cho2, Kwang Jin Lee1, Boreom Lee1  
1Department Of Medical System Engineering, GIST, Gwangju/KOREA, 2Mechatronics, gwangju institute of science and technology, Gwangju/KOREA

I. INTRODUCTION

In recent years, a lot of researchers have tried to construct the system to recognize a hand or finger gesture based on the surface electromyogram (sEMG) since it can be used for the human computer interface.

They have only focused on recognizing simple movements such as an extension or flexion of fingers. However, in our present study, we propose a system to recognize a pinch-to-zoom gesture in real-time for practical applications. Pinch-to-zoom is a gesture to change the distance between the thumb and index fingers in order to control the size of images. For inferring the gesture, sEMG was acquired from the first dorsal interosseous muscle and multiclass classification techniques were used.

II. METHODS

A. Experiment and System settings

We recruited six healthy subjects for our experiment. We asked subjects to maintain the distance between thumb and index finger according to the visual cues (0 cm, 4 cm, 8 cm, and 12 cm).

Our system is divided into a sensor interface and computational unit parts. The sensor interface wirelessly transmits the sEMG to computational unit using Bluetooth. We developed graphic user interface (GUI) based on Matlab. The software reduces the noise, extracts the features and provides a visualization of the distance between the thumb and index finger in real time. (See figure1)

B. Feature extraction and Classification

In order to identify the distinct frequency bands, ANOVA test was conducted between four experimental conditions. Consequently, the powers from 1Hz to 250Hz are statistically significant (p < 0.01). Therefore, the powers from 1Hz to 250Hz were used as features for pinch-to-zoom gesture recognition.

The support vector machine (SVM) was used for recognizing the pinch-to-zoom gesture. Several hyperplanes have to be used for solving an N-class problem (N > 2) because SVM is based on two-partitions. As a result, average classification rate over all subjects was about 91.9%. These results prove that our system can be successfully used for recognizing the pinch-to-zoom gesture in real time.

SP031.2 - Feature extraction trends for biomedical signals

**Author(s):** Yashodhan Athavale1, Sridhar Krishnan2  
1Electrical & Computer Engineering, Ryerson University, Toronto/ON/CANADA, 2Electrical & Computer Engineering, Ryerson University, Toronto/CANADA

Signal analytics involves identifying signal behavior, extracting linear and non-linear properties, compression or expansion into higher or lower dimensions, and recognizing patterns. Over the last few decades, signal analytics has taken notable evolutionary leaps in terms of measurement – from being simple techniques for analyzing analog/digital signals in time/frequency/joint time-frequency (TF) domain, to being complex techniques for analysis in a higher dimensional sparse domain. The intention behind this is simple – Feature Extraction; i.e. to identify specific signal markers or properties exhibited in one phenomenon, and uses them to distinguish from properties exhibited in another phenomenon [1-9].

One must realize that real world biomedical signals are non-linear, non-stationary and could comprise of multi-modal components. Evolutionary methods such as Autoregressive modeling, Cepstrum modeling, and Fourier and Wavelet analysis can handle non-stationarity through windowing approaches [7, 9], but with certain limitations such as information loss, lower artifact filtering and low signal-to-noise & distortion-ratio (SNDR). We suggest that modern day feature extraction methods must be as intelligent and trainable as the pattern classifier itself. Ideally instead of windowing, it is recommended to handle real-time signals using a streaming or on-the-fly approach, i.e. extract features as the signal propagates through the source. This could be made possible by employing newer sparse and compressive sensing approaches in combination with TF methods such as non-negative matrix factorization; or even a deep learning network constructed using a cascade of wavelet filters. An intelligent feature extractor could possibly eliminate the need for a feature selection technique (such as mRMR - minimum redundancy maximum representation), as this would happen inherently within the feature extractor. Additionally if the features are visually separable between signal classes, then employing a simple linear classifier could reduce system design constraints thus impacting the hardware design positively. Through this study we are attempting to
determine the best combination of signal processing methods which could generate an intelligent feature extractor capable of: [i] robustness to artifacts, [ii] improving SNDR, [iii] handling non-linearity, [iv] handling non-stationarity, [v] assessing signal component variability, [vi] addressing higher dimensionality of feature space by compact or sparse feature generation, and most importantly [vii] generating a feature set which brings out maximum representation of the signal and helps pattern classification. From a hardware perspective we should also include the following criterion: [i] built-in pre-processing and artifact removal, [ii] low power and memory consumption, [iii] real-time signal processing capability and [iv] computationally cost effective.

**SP031.3 - A Hybrid Model for Diagnosing Sever Aortic Stenosis in Asymptomatic Patients using Phonocardiogram**

**Author(s):** Arash Gharehbaghi¹, Per Ask², Eva Nylander³, Birgitta Janerot-Sjoberg⁴, Inger Ekman³, Maria Lindén¹, Ankica Babic²

¹Department Of Innovation, Design And Technology, Mälardalen University, Västerås/SWEDEN, ²Department Of Biomedical Engineering, Linköping University, Linköping/SWEDEN, ³Department Of Clinical Physiology, Linköping University, Linköping/SWEDEN, ⁴Department Of Clinical Science, Intervention And Technology, Karolinska Institutet, Stockholm/SWEDEN

This study presents a screening algorithm for severe aortic stenosis (AS), based on a processing method for phonocardiographic (PCG) signal. The processing method employs a hybrid model, constituted of a hidden Markov model and support vector machine. The method benefits from a preprocessing phase for an enhanced learning. The performance of the method is statistically evaluated using PCG signals recorded from 50 individuals who were referred to the echocardiography lab at Linköping University hospital. All the individuals were diagnosed as having a degree of AS, from mild to severe, according to the echocardiographic measurements. The patient group consists of 26 individuals with severe AS, and the rest of the 24 patients comprise the control group. Performance of the method is statistically evaluated using repeated random sub-sampling. Results showed a 95% confidence interval of (80.5%-82.8%) / (77.8%- 80.8%) for the accuracy/sensitivity, exhibiting an acceptable performance to be used as decision support system in the primary healthcare center.

**SP031.4 - Classification of Load in Hands Based on Upper Limb SEMG**

**Author(s):** Illya Seagal, Evelyn Morin

Electrical & Computer Engineering, Queen's University, Kingston/ON/CANADA

The purpose of this study is to correctly classify load lifted during a pail lift task. Surface EMG (SEMG) data were recorded from six locations on the arm and trunk of 15 subjects. Each subject was asked to lift a pail with one hand onto a platform at waist height in front of him/her. The pail contained masses from 0 kg to 20 kg in increments of 5 kg. Each weight was lifted and set down 5 times. The down-lift interval of the task was identified from a recording of an electro-mechanical switch and SEMG data from the triceps brachii and brachioradialis were extracted. The data were filtered for noise reduction using a 12th order high pass Type II Chebyshev filter with a cut-off frequency of 25 Hz, and a low pass 1st order Butterworth filter with a cut-off frequency of 490 Hz. The mean absolute value (MAV) and RMS value were computed and used as a feature set. A hierarchical SVM system shown in Figure 1 was used to classify the load lifted.

Overall the mean inter-subject classification success rate for classifiable trials was 0.490 using a train on 1st subject and test on others scheme, and 0.483 using a train on 1st trial and loads of all subjects and test on all other trials scheme. The combined confusion matrix for the former scheme can be seen below. Using simple features and a hierarchical SVM structure, a reasonable inter-subject classification accuracy was achieved. This outcome may be improved in the future by careful selection of additional features.
An Intelligent Method for Discrimination between Aortic and Pulmonary Stenosis using Phonocardiogram

**Authors:** Arash Gharehbaghi, Amir A. Sepehri, Armen Kocharian, Maria Lindén

1Department Of Innovation, Design And Technology, Mälardalen University, Västerås/SWEDEN, 2CAPIS Biomedical Research and Department Center, Mons/BELGIUM, 3Department Of Pediatrics, Tehran University of Medical Sciences, Tehran/IRAN

This study presents an artificial intelligent-based method for processing phonocardiographic (PCG) signal of the patients with ejection murmur to assess the underlying pathology initiating the murmur. The method is based on our unique method for finding disease-related frequency bands in conjunction with a sophisticated statistical classifier. Children with aortic stenosis (AS), and pulmonary stenosis (PS) were the two patient groups subjected to the study, taking the healthy ones (no murmur) as the control group. PCG signals were acquired from 45 referrals to the children University hospital, comprised of 15 individuals of each group; all were diagnosed by the expert pediatric cardiologists according to the echocardiographic measurements together with the complementary tests. The accuracy of the method is evaluated to be 90% and 93.3% using the 5-fold and leave-one-out validation method, respectively. The accuracy is slightly degraded to 86.7% and 93.3% when a Gaussian noise with signal to noise ratio of 20 dB is added to the PCG signals, exhibiting an acceptable immunity against the noise. The method offered promising results to be used as a decision support system in the primary healthcare centers or clinics.

SP032.1 - NEUROPROSTHETIC SYSTEMS FOR ENHANCEMENT OF NEUROPLASTICITY FOLLOWING STROKE AND SPINAL CORD INJURY

Author(s): Milos Popovic
Toronto Rehabilitation Institute, University Health Network, Toronto/Canada

In this lecture three neuroprosthetic applications will be presented that do not belong to a typical “garden variety” neuroprostheses that one can commonly find discussed in the literature. The first part of the lecture will showcase a neuroprosthetic application, which is aimed at restoring voluntary hand function after severe stroke. In the lecture the results of a Phase II randomized control trial will be presented, which were pivotal for this technology to become a commercially viable product. The second part of the lecture will discuss a neuroprosthetic system for blood pressure regulation for individuals who suffer from orthostatic hypotension following spinal cord injury. In the lecture the results from a Phase I clinical trial will be presented. The third part of the lecture will showcase use of electrical stimulation technology as means to navigate stem cell migration. In the lecture the proof of principle results will be presented. These three projects have been selected to showcase idea generation, product development and clinical trial validation process commonly practiced at the Rehabilitation Engineering Laboratory. The second objective of this lecture is to stress the importance of system level engineering, as a critical tool in the process of creation, development and validation of neuroprosthetic devices.

SP032.2 - Demonstration of Graphene Microelectrodes as a Bioelectronic Interface

Author(s): Michael R. Horn, Arika D. Kemp, Keong H. Yong, Jong-hyun Choi, Sungwoo Nam, Ken Yoshida
1Biomedical Engineering, Indiana University Purdue University Indianapolis, Indianapolis/IN/UNITED STATES OF AMERICA, 2Mechanical Science And Engineering, University of Illinois at Urbana-Champaign, Urbana/IL/UNITED STATES OF AMERICA

In the past 15 years, our lab has developed interfascicular microelectrode arrays (MEAs) for use in the peripheral nerve based upon micropatterned polyimide substrates with metal traces and contacts. These were the thin-film Longitudinal Intra-Fascicular Electrode (tLIFE) and the Transversely Implanted Micro-Electrode array (TIME). Acutely, these electrodes provide a high resolution view of the nerve activity within a nerve fascicle as well as a high resolution means to activate subsets of the nerve bundle. In part, the use of polyimide as the substrate material was to reduce the mechanical property mismatch between the neural tissues and the electrode structure as a means improve the chronic viability of the neural interface. However, chronic implants of tLIFE and TIME structures have shown that despite being several orders of magnitude softer than metal wire electrodes, (~1GPa vs ~150 GPa), the structures became encapsulated in a similar fashion to the metal wire electrodes. It has become clear that the 2 orders of magnitude reduction in modulus was not a sufficiently large enough reduction to show a change in encapsulation of the electrodes in the peripheral nerve, which has a modulus of elasticity of ~100kPa.

We are currently exploring newer softer materials for the substrate, with moduli on the order of 1GPa. However, substrates of softer materials will require traces and contacts that can withstand 10-15% elongation. This pilot study, we explored such a material, graphene.

Analysis of whether a graphene microelectrode array could measure the bioelectrical activity of muscle tissue as a first step towards developing a general purpose ultraflexible neural or muscular bioelectric interface. A graphene MEA (graMEA) was placed on the surface of an ex vivo rat biceps femoris muscle, and the electrical activity resulting from electrical stimulation of the sciatic nerve was recorded. The resulting twitch activity was simultaneously recorded using conventional intramuscular wire electrodes. It was found that the graMEA was capable of measuring stimulus artifact, compound EMG of the twitch and mechanical movement of the muscle, as shown below. Further advancements to the graphene based electrode include increasing the surface area by crumpling, reducing the contact size to increase spatial resolution of small nerve fibers, and using a field-effect transistor (FET) mode to increase signal to noise ratio. The results of this study provide proof of concept that flexible graphene electrodes can transduce bioelectrical activity of bioelectrically active tissues, opening the way towards developing ultra-small, ultra-flexible bioelectric interfaces.
Previous studies and experimental evidences suggest an important role of extracellular electrical cue in the establishment of photoreceptor cell polarity and polarization of intracellular structures, to analyze the special role of an extracellular electrical cue. Using a well-established migration assay, photoreceptors cone-like 661W mouse retina cells were stimulated for 5 h with 5 VDC/cm electric field. Using immunofluorescence techniques we have investigated changes in position of important organelles like Microtubules Organizing Center (MTOC), Golgi Apparatus (GA) and nucleus within those cells after the stimulation. In response to the directional stimulus, the cells have extended membrane protrusions towards the cathode; they got elongated perpendicular to the dcEF and have formed a leading edge towards the direction of cues. Directional migration has occurred towards cathode. MTOC and GA were reoriented in the direction of the leading edge of the cells (cathode), while the nucleus was translocated to the back of the cells, in the rear edge. Nuclear positioning is determined by microtubule and actin networks. The Golgi complex was colocalized with the MTOC in order to facilitate polarized secretion and provide membrane and secreted products directly to the most proximate plasma membrane to the leading edge of migrating cells.

**SP032.5 - Accelerating Neurite Outgrowth Through Electric Field Manipulation**

**Author(s):** Michael T. Purdy¹, Pierre J.J. Wijdenes¹, Wali Zaidi², Naweed Syed³, Colin Dalton³

¹Biomedical Engineering Program, University of Calgary, Calgary/AB/CANADA, ²Department Of Anatomy And Cell Biology, University of Calgary, Calgary/CANADA, ³Department Of Electrical And Computer Engineering, University of Calgary, Calgary/CANADA

Brief electrical stimulation accelerates neuronal regeneration both in individual cells and in living models. In vitro experiments facilitate further understanding of regeneration mechanisms, and stimulation is accomplished through current-injecting micropipettes or commercially available micro electrode arrays. Such stimuli can be approximated as point-sources that emit decaying electric fields with high magnitude field strength near the electrode or micropipette. However, uniform electric fields may be better suited to enhance growth than traditionally used point-source fields. Applied uniform electric fields would allow for long distance stimulation without requiring high voltages that can compromise electrode integrity and cell health. The viability of uniform electric field stimulation was explored in this study through the use of a custom-fabricated planar microelectrode array. Simulation of several electrode configurations resulted in the design of a parallel plate anode-cathode pair. Several electrode pairs were embedded onto a single microelectrode array at various gap widths, to allow for the study of electric field strength on overall growth. With this novel electrode array, individual Lymnaea snail cells were stimulated with a 20 Hz, 1 volt pulse train for one hour. Control cells were plated on identical electrode arrays but were not connected to the stimulus generator. The impact of stimulation on growth was measured 24 hours later, and compared to control groups (Fig. 1). Stimulated cells showed an increase in neurite length compared to controls (Fig. 2). This effect was seen regardless of stimulus magnitude, within the range of 1000 - 2000 mV/mm. Our preliminary study served as a proof of principal for the application of uniform electric fields as a regenerative technique for nerve regrowth. The designed electrode layout improves upon currently available micro electrode arrays, and will allow for further study of regeneration mechanisms. This layout will be more easily transferred to an implantable design for future clinical use.
**SP033.1 - Quantification of breast density using dual-energy mammography, CT and MRI**

**Author(s):** Sabee Molloi, Huanjun Ding  
Radiological Sciences, University of California, Irvine/UNITED STATES OF AMERICA

Breast cancer is the most common cancer and the second leading cause of death from cancer. Mammographic density, which is defined as the ratio of fibroglandular tissue to the total fibroglandular and adipose tissue, is an important risk factor in the development of breast cancer. It has been shown that women with the highest mammographic density (75%–100% fibroglandular volume) have four- to fivefold increased risk of developing breast cancer compared with the lowest density (0%–25% fibroglandular volume). The current standard of care for breast density evaluation involves visual assessment of mammograms. This subjective classification scheme is limited by its considerable intra- and inter-reader variability. Additionally, an important limitation is that an area measurement using mammography ignores the physical 3D character of a real breast. Breasts of different thicknesses can potentially all yield the same measurement of area breast density yet correspond to widely varying volumetric breast density values. Volume-based techniques, which overcome some of the limitations of area-based techniques, include using dual-energy mammography, CT and MRI. Currently, there is no accepted standard for measuring breast density and accuracy of different techniques is not known. Postmortem breast studies were performed to assess the accuracy of breast density measurement for dual-energy mammography, spectral CT, dual-energy cone-beam CT, cone-beam CT and MRI. 40 postmortem breasts were imaged using a dual-energy mammography system. Glandular and adipose equivalent phantoms of uniform thickness were used to calibrate a dual-energy basis decomposition algorithm. Dual-energy decomposition was applied after scatter correction to calculate breast density. Breast density was also estimated using percent volumetric measures described in BI-RADS, standard histogram thresholding and a fuzzy C-mean (FCM) algorithm. The postmortem breasts were also imaged using spectral CT based on CZT photon-counting detectors, dual-energy cone-beam CT and breast MRI. Finally, breasts were chemically decomposed to measure the definitive tissue composition, in terms of water, lipid, and protein. The left-and-right correlations were used to estimate the precision of each technique. The percent fibroglandular volume (%FGV) from chemical analysis was used as the reference standard to assess the accuracy of different techniques to measure breast composition. In the left-and-right comparisons, the standard error estimation (SEE) was calculated to be 9.1%, 9.1%, 9.2% and 4.6% for BI-RADS, standard histogram thresholding and a fuzzy C-mean (FCM) algorithm. The postmortem breasts were also imaged using spectral CT based on CZT photon-counting detectors, dual-energy cone-beam CT and breast MRI. Finally, breasts were chemically decomposed to measure the definitive tissue composition, in terms of water, lipid, and protein. The left-and-right correlations were used to estimate the precision of each technique. The percent fibroglandular volume (%FGV) from chemical analysis was used as the reference standard to assess the accuracy of different techniques to measure breast composition. In the left-and-right comparisons, the standard error estimation (SEE) was calculated to be 9.1%, 9.1%, 9.2% and 4.6% for BI-RADS, standard histogram thresholding, FCM, and dual-energy mammography, respectively. In correlation to %FGV from chemical analysis, SEE was calculated to be 9.9%, 8.6%, 7.2% and 4.7% using quartile volumetric rankings, standard histogram thresholding, FCM, and dual-energy mammography, respectively. The accuracy of breast density measurement for spectral CT, dual-energy cone-beam CT, cone-beam CT and MRI were calculated to be 2.8%, 3.6%, 3.9%, and 6.5%, respectively. In conclusion, the results indicate that dual energy mammography can be used to accurately measure breast density. The variability in breast density estimation using dual energy mammography was substantially lower than quartile volumetric rankings, standard histogram thresholding, FCM and breast MRI. The results also suggested that spectral CT is a very promising technology for breast imaging.
SP033.2 - Study on the Main Nonconformities Found in no Mammography Alagoas State

**Author(s):** Jose R. Almeida Nato¹, Cinhia M.M. Paschoal³, Divanizia D.N. Souza³, Lourdes M. Brasil³, Fernanda C.L. Ferreira³

¹Physics, State University of Health Sciences of Alagoas, Alagoas/BRAZIL, ²Civil Engineering, State University of Vale do Acaraú, Sobral/CE/BRAZIL, ³Physics, Federal University of Sergipe, São Cristóvão/BRAZIL, ⁴University of Brasilia, Brasilia/BRAZIL, ⁵Federal University of South and Southeast of Pará, Marabá/BRAZIL

Mammography is one of the most important radiological techniques in tracking and control of the breast cancer development; capable to accurately identify the absence or presence of diseases, which can assist in the definition of reliable reports in case of viewing any types of anomaly. In this sense, the aim of this work was to conduct a study of the major non-conformities found in mammograms operating in the State of Alagoas, Brazil, warning the risk of negative and false positive diagnosis. In this work, main non-conformities found in the mammography’s equipment of the state are prioritized, such results were classified as compliant and non-compliant according to the guidelines established by the National Agency for Sanitary Vigilance. Following this approach, XLV Diagnostics, a Canadian start-up, is capitalizing on their low cost components to drive down significantly the cost of medical imaging equipment. A higher percentage of non-compliance were A1, B2 and B5, as well, may be recommended that the mammography equipment such institutions should undergo maintenance process and rigorous calibration and frequent quality control tests. Mammograms’ tests A3, A4 and B1 showed satisfactory results, with compliance above 90% within the parameters established by Decree 453 of National Agency for Sanitary Vigilance. Focusing on all mammograms, it becomes necessary to implement a quality control program and will show several of its parametric characteristics.

SP033.3 - Affordable medical x-ray imaging for the developing world: a global vision

**Author(s):** Sorin Marcovici², Vlad Sukhovatkin², Oscar Cisek²

²XLV DIAGNOSTICS INC., Thunder Bay/CANADA, ³XLV DIAGNOSTICS INC, Thunder Bay/ON/CANADA

Imaging technologies, already used routinely for diagnostics, are becoming an essential part of the work flow included in screening, treatment progress monitoring and outcome evaluation. However, various imaging modalities considered standard practice for the medical institutions in the developed world remain today rather inaccessible for the populations at large in the developing countries. One of the limiting factors is the high cost of medical imaging equipment.

To develop and produce low cost, medical imaging systems of good quality requires disruptive innovations and novel approaches to engineering. The sophistication and capabilities of ubiquitous consumer products available today provide a real opportunity to capitalize on their low cost components to drive down significantly the cost of medical imaging equipment.

Following this approach, XLV Diagnostics, a Canadian start-up, is developing a completely new technology, X-ray Light Valve (XLV), for producing very affordable large area, flat panel, x-ray detectors based on which economical medical imaging systems can be built. The first XLV product will be a digital mammography machine for breast cancer screening that will be sold at a fraction of the price asked for presently available machines.

The paper will present the conceptual approach and innovative engineering to create from consumer type components a good quality digital imaging system and will show several of its parametric characteristics.

SP033.4 - Characterization and Analysis of the Physical Parameters in Dental X-Rays Phantom

**Author(s):** Lilian F. Silva¹, Jhonatan M. Santos¹, Cinhia M.M. Paschoal³, Divanizia D.N. Souza³, Lourdes M. Brasil³, Fernanda C.L. Ferreira³

¹Federal University of South and Northeast of Pará, Marabá/BRAZIL, ²Civil Engineering, State University of Vale do Acaraú, Sobral/BRAZIL, ³Physics, Federal University of Sergipe, São Cristóvão/BRAZIL, ⁴University of Brasilia, Brasilia/BRAZIL

All care related to ionizing radiation exposure to patients, the radiographic image quality and gain time is related to quality control equipment and image. Therefore, it is necessary to be realized by using quality control and intercomparison phantom images with the results of previous tests as well as other types of X-ray equipment, or performing the intercomparison of results of quality control testing. The objective of this study was to characterization, and analysis (intercomparison) results periapical radiographs obtained with phantom and evaluate the high and low contrast in dental radiographs service of Maraba, northern Brazil. For the intercomparison of physical parameter of high and low contrast in the periapical radiographic equipment of the Maraba, a phantom developed in Brazil was used precisely in Aracaju, northeastern. It is worth noting that, the phantom used in this work and the interparameter of the equipment of the images showed satisfactory results bringing out the difference from the standard image. However, tests can be used to switch to other equipment in the surrounding towns of the city of Maraba. Thus allowing the cornerstone for the creation of a database with images obtained with the phantom and can be used in training of students and dental professionals.

SP033.5 - In Vitro and In Vivo Studies Glycosylated Gadolinium Nanomagnetic Particles (GD-DTPA-DG) as New Potential Metabolic Contrast Agent in MMRI

**Author(s):** Sara -, Heydarnezhadi, Nader Riyahi-Alam, Soheila Haghgoo, Ensieh Gorji, Hosein Ghenaati, Behrouz Rafiei

Tehran university of Medical Science, tehran/IRAN

Early cancer diagnosis using MRI imaging is of high global interest as a noninvasive and powerful modality in molecular imaging. Therefore demand for new MRI contrast agents, with an enhanced sensitivity and advanced functionalities that improve the targeting to specific tissues or organs, is very high. In this study, D-glucose amine was conjugated to a well-known chelator, diethylenetriamine penta-acetic acid (DTPA), then labeled with Gd to achieve Gd-DTPA-DG, Which is a metabolic contrast agent in mMRI. The contrast agent was synthesized and characterized physicochemical using different techniques including dynamic light scattering (DLS), high resolution transmission electron microscopy (HTEM) and inductively coupled plasma atomic emission spectroscopy (ICP-AES), Efficacy of the targeted contrast agent was assessed by measuring relaxation rate in vitro and tumor MR imaging were performed to determine signal intensity (SI) in vivo (0.1 mmol Gd/kg) in female balb/c mice mod-el. According to the results, the nano metabolic contrast agent penetrate into cells and accumulated in tumor, which cause improve the contrast of tumor tissue in comparison with magnevist. The results showed that the novel nano contrast agent could become useful tool in early detection of cancer.
SP034 - CT: New Techniques

SP034.1 - Design, modeling and performance evaluation of a small animal Micro-CT scanner: A Monte Carlo study
Author(s): Samira Nezhaddeghani, Saeed Sarkar, Mohammad Reza Ay
Department Of Medical Physics And Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN

Introduction: Nowadays, by increasing the interest in the use of small animals in biomedical studies, development of small animals imaging systems such as Micro-CT scanners are promoted. Development of the hybrid systems such as SPECT/CT is the other significant factors in development of this kind of scanners. The diagnostic power will be increased by superposition anatomical and functional images in hybrid systems. Furthermore, obtained attenuation map from Micro-CT can be used for attenuation correction of the SPECT data. The purpose of this study was to design and improves the performance of Micro-CT scanner to develop a small animal SPECT/CT system by using the Monte Carlo simulation. The SPECT module called HiReSPECT already fabricated in our Laboratory.

Materials and Methods: In this study the GATE Monte Carlo package was used for accurate modeling of the system, the tube voltage 30-70 kV with focal spot size 30 µm, anode from Tungsten and aluminum filter with thickness of 0.5 mm. The designed detection system has dimension 5.0 x 18.5 x 4.7 cm³ with 100 microns pixels size and an indirect flat-panel scintillator made from CsI(Tl). In this study, the selected distance from the X-ray tube to object 10-12 cm and distance from object to detection system 8-10 cm was considered. These distances were chosen base on the separation length between two detectors and diameter of gantry of HiReSPECT. In analysis and post process the results of the simulation, spatial resolution, noise, contrast and scatter to primary ratio (SPR) was investigated and an optimal design for the scanner detector was presented. The computerized phantom (MOBY) was implemented in simulated scanner and reconstructed images provided by using MATLAB program.

Results: Tomographic image of the simulated phantom containing nine cylinders with radial 0.5, 1, 2.5 and 5 mm which were considered filled with tissue equivalent material like skull, lung,ribbon and cartilage were represented the designed system is capable to distinguish soft tissue materials and demonstrate 0.5 mm resolution of the skull (Fig 1-B). The achieved spatial resolution for different materials and dimensions varied in the range of 100 to 150 µm with 0.03% of the noise and 0.0015 of SPR.

Conclusion: In this study, a Micro-CT scanner was simulated with GATE Monte Carlo code by considering geometrical limitation of HiReSPECT. Finally all of mentioned parameters were optimized and were obtained good images of it.

Fig. 1 A) Simulated phantom using GATE code; B) Reconstructed

SP034.2 - An imaging method by using electron mode of linear accelerator for soft tissue emphasis
Author(s): Atsushi Muroyama, Hidetoshi Saitoh
Radiological Sciences, Tokyo Metropolitan University, Tokyo/JAPAN

Purpose
Megavoltage portal images are used to verify the proper positioning of the patient in image-guided radiation therapy (IGRT). However, the description of low density material reconstructed by MV image doesn’t reach kilovoltage one because the flattening filter of linear accelerator causes beam hardening and an increase of scattered photon. To solve this problem, we designed a new image acquisition method by using electron mode of linear accelerator. The low contrast image is acquired by this method because the focus of the target becomes large by attaching to the shadow tray of a linear accelerator, and because Mega-voltage X-rays cause Compton scattering much within human body. To approach those problems, in this study, we propose a 2-pass 3D image reconstruction using simple Monte Carlo method. Feld Kamp, Davis and Kress (FDK) method was used for 3D reconstruction, and BEAMnrc based simple Monte Carlo method was developed to estimate scattering photons.

Method
The portal images were taken by using bremsstrahlung x-ray that was generated by the target newly attached under secondary collimators. To estimate scattering photon, 3D reconstruction was performed in two steps. By the first step, the rough structure was reconstructed by FDK method. In this step, graphic processing unit (GPU) was utilized to reduce the processing time. In this study, a NVIDIA GeForce GTX970 (CUDA) was used for parallel processing. By the next step, the simulation for investigating the relation between the generating position of a scattering photon and EPID data was performed by using the first reconstructed data. Although the most reliable method was Monte Carlo simulation, that was time consuming process and was not practical. Therefore, simple Monte Carlo (SMC) using GPU acceleration was proposed. Although some SMC was proposed, we chose the method of holding and reusing in a memory the result of the full Monte Carlo that was calculated beforehand. In this method, BEAMnrc code system was used for estimating position of scattering photon in an object. Since it was necessary to perform our method for every rotation angle of a gantry, the proposed method needed high-speed processing. This method was accelerated by holding beforehand the full Monte Carlo calculation result to the HU range of primary reconstruction data. Aluminum target were selected for proposed method. This method was simulated and measured on 4, 6 and 9 MeV electron beam.

Result and Conclusion
The calculation time of proposed SMC was about 9 seconds per one projection. The processing time consumed to 180 projections was 27 minutes. The result images emphasized soft tissue than the images acquired by high energy X-ray.

SP034.3 - Anatomical noise model for CT head images: preliminary results
Author(s): Rafael A. Miller-Clemente1, Marlen Perez-Diaz2
1Group Of Radiation Medical Physics, Biofísica Médica, Santiago de Cuba/CUBA, 2Study Center On Electronic And Information Technologies, Universidad Central Marta Abreu de las Villas, Santa Clara/ CUBA

The availability of an anatomical predictive noise model provides new knowledge about the physical factors tradeoff and the quantitative effect of multiple factors over the diagnostic image quality. Here,
the anatomical noise was defined as the standard deviation of pixel intensities, contained in a region located at the center of an axial CT pediatric head image. Images were obtained by using an Automatic Exposure Control system. The purpose of this work was to determine the association between the noise on diagnostic images and a noise model based on phantom measurements. The model of anatomical noise obtained has an adequate predictive value, with a correlation coefficient of 0.97 (significance level of 95%) and mean square error of $1.9 \times 10^{-6}$.

SP034.4 - The potential of spectral-CT for material decomposition with gold-nanoparticle and iodine contrast

Author(s): Byungdu Jo
Department Of Radiological Science, College Of Health Science, Yonsei university, Wonju/KOREA

The objective of the this study was to demonstrate feasibility of using gold contrast-agent as a new contrast agent for spectral-computed tomography (CT) system and decompose the iodine and gold materials in the spectral-CT system using K-edge imaging technique. Recently, gold based nanoparticles contrast-agent has been introduced for vulnerable plaque imaging in CT system. The spectral-CT system equipped with Cadmium Zinc Telluride (CZT)-based photon-counting detector has energy-discrimination capabilities and high resolution image acquisition capabilities. We performed a simulation study using the Geant4 Application for Tomographic Emission (GATE) simulation. The CZT detector contained four CZT crystals and total detector length was 51.2 mm with 64-channel array. The results showed that the contrast-to-noise ratios of iodine and gold contrast-agent materials in energy window included K-edge energy of materials (33-49 keV for iodine, 66-81 keV for gold) were increased approximately 1.9 and 1.7 times higher than others. These results also show the possibility of potential of using two contrast-agents at a time to provide the various information of image such as plaque vulnerability assessment.

SP034.5 - Spatial Resolution Studies for a Prototype Proton CT Scanner

Author(s): Tia E. Plautz1, Robert P. Johnson1, Hartmut F.-. Sadrozinski2, Andriy Zaterklyanyan3, Vladimir Bashkirov2, Reinhard W. Schulte2, Robert F. Hurley2, Valentina Giacometti3
1Scipp, University of California, Santa Cruz, Santa Cruz/CA/UNITED STATES OF AMERICA, 2Radiation Research Laboratories, Loma Linda University, Loma Linda/UNITED STATES OF AMERICA, 3Centre For Medical Radiation Physics, University of Wollongong, Wollongong/NSW/AUSTrALIA

We report on the simulation and initial beam test results with the pre-clinical (phase II) head scanner developed for proton computed tomography (pCT) by the pCT collaboration. In the future, proton CT may be employed to improve the accuracy of relative stopping power functions required for image reconstruction. The Phase II proton CT system consists of two silicon telescopes that track individual protons before and after a phantom, and a novel 5-stage scintillation detector that measures a combination of the residual energy and range of the proton. Residual energy is converted to water equivalent path length (WEPL) of the protons in the scanned object. The set of WEPL values and associated paths of protons passing through the object over a 360° angular scan is processed by an iterative parallelizable reconstruction algorithm that runs on GP-GPU hardware. This report will focus on studies of the spatial resolution of the phase II imaging system, while studies of the achievable accuracy of relative stopping power will be reported elsewhere. A custom edge phantom composed of water-equivalent polymer with 4 body-equivalent material inserts was developed. The phantom was first simulated using Geant4 and then built for experimental beam tests with 200 MeV protons at the research beam line at the Loma Linda University Medical Center. A modified version of the oversampling method was used in order to construct edge spread functions and modulation transfer functions for materials of varying relative stopping powers located at several radial displacements from the center of the phantom. A combination of angular cuts with the aim to eliminate large-angle scattered protons, the most likely path (MLP) concept, and a superiorization method in iterative image reconstruction are used to improve the spatial resolution of the image reconstruction. These sophisticated and computing-intensive techniques are being compared to simpler and much faster reconstruction methods including filtered back projection along curved paths and cubic-spline path approximation. Reconstructions of pCT data sets obtained with a realistic anatomical head phantom will further complement the analysis of the MTF.

SP034.6 - Influences of object size and tube potential pairing on the accuracy of iodine quantification using dual energy CT

Author(s): Josh Grimes, Lifeng Yu, Shuai Leng, Cynthia Mccollough
Mayo Clinic, Rochester/MN/UNITED STATES OF AMERICA

Purpose: The objective of this study was to evaluate the accuracy of iodine quantification in phantom images acquired on a dual-source dual-energy CT scanner. The influences of phantom size and different tube potential pairs were investigated.

Methods: Three bottles with iodine concentrations of 3.5, 7 and 10.5 mg/mL were placed inside 8 torso-shaped water phantoms ranging from 15 to 50 cm in lateral width. Dual energy scans of each phantom were acquired on a dual-source CT system (Siemens Somatom Force) using 4 different tube potential pairs (low energy: 70, 80, 90, and 100 kV; high energy: 150 kV + 0.6 mm Sn). CTDIvol was matched for all scans of a given phantom size. Images were reconstructed with 1-mm image thickness at 0.8 mm intervals using a medium smooth body kernel. The dual-energy data were post-processed using commercial software (syngo Via Dual Energy, VA30), which generated virtual non-contrast and iodine overlay images. Iodine concentration (in mg/mL) was displayed for regions of interest drawn over the iodine bottles, and compared with the known concentrations for each phantom size and tube potential pairing.

Results: At 70/150Sn, the measured iodine concentration was within 9% of the known concentration for phantom sizes from 15-45 cm. However, images acquired at 70/150Sn were deemed unacceptable for phantom sizes greater than 35 cm due to ringing artifacts. At 80/150Sn, 90/150Sn and 100/150Sn, iodine concentrations determined for phantom sizes up to 45 cm agreed with known concentrations within 14%, 25% and 19%, respectively. At 100/150Sn, the iodine concentration in the 50 cm phantom was within 27% of the known value. Iodine quantification was most accurate (within 2% for all tube potential pairs) for the highest iodine concentration (10.5 mg/mL) in the 30 cm phantom. As phantom sizes increased or decreased from 30 cm, iodine concentration was increasingly overestimated.

Conclusion: The accuracy of iodine quantification depends strongly on the phantom size. When selecting the tube potential pairing, both image quality (e.g. artifacts) and accuracy of measured iodine concentration should be considered.

SP034.7 - Characterization of Vulnerable Plaque with Dual-Energy during CT Coronary Angiography: A Phantom Study

Author(s): Ali Ursani1, Sachin Moghe2, Carlton Hoy3, Narinder Paul4

1Medical Engineering, University Health Network, Toronto/ON/CANADA, 2Toshiba Medical Research Institute, Toshiba Medical USA, Vernon Hills/L/UNITED STATES OF AMERICA, 3Mechanical & Industrial Engineering, University of Toronto, Toronto/ON/CANADA, 4Medical Imaging, University Health Network, Toronto/CANADA

PURPOSE/AIM:

The aim of this exhibit is to: Demonstrate the utility of Dual Energy image acquisition and post processing to provide high-resolution characterization of mixed arterial plaque in an anthropomorphic coronary artery phantom composed of tissue equivalent materials. Introduce the concept of a Dual Energy index and material decomposition algorithm.

CONTENT ORGANIZATION:

Description of the Dual Energy Coronary Artery Phantom containing arteries with variable degrees of lumen stenosis Specifications for the mass attenuation properties of materials mimicking the spectrum of calcified and non-calcified vulnerable plaque Validation of attenuation properties of phantom based materials compared to biological tissues compared at different energies. Calculation of Dual Energy Index and energy - attenuation plot for iodine and calcium based materials present in the phantom. Use of Dual energy material decomposition software to generate iodine and calcium removed images to improve accuracy of stenosis assessment.

RESULTS SUMMARY:

A tissue equivalent coronary artery phantom is extremely useful in demonstrating significant improvements in accuracy of stenosis measurement and characterization of vulnerable coronary artery plaque with Dual Energy image acquisition and post processing.
Osteoarthritis (OA) is a debilitating chronic joint disease that is becoming a growing concern among the aging population. Due to its complex nature, many questions regarding its initiation and progression remain unanswered. There has been a renewed interest in the bone-associated vasculature, and the role they may play in OA. Thus, having the ability to quantify and characterize the vascular changes (patency, density, and micro-architecture) provide more information into OA’s initiation and progression.

Micro-computed tomography (micro-CT) is widely used for its ability to provide well-characterized bone. However, the visualization of associated vasculature is difficulty due to their (1) size (5-10 μm for capillaries), (2) poor inherent x-ray contrast, and (3) proximity to highly x-ray attenuating bone. We propose the combination of a custom exogenous vascular perfusion contrast agent, dual-energy micro-CT (DECT), and decomposition algorithms to allow for the distinct and separate visualization of the perfused vasculature and bone.

To demonstrate the capabilities of our combination technique, a lanthanide-based vascular perfusion contrast agent and x-ray filter was developed. We perfused the lower half of a rat with our vascular contrast agent through the aorta and embedded the excised left hindlimb in agar. The sample was then scanned on our GE Vision120 phantom with cardiac insert, filled with 99mTc, simulating a SPECT myocardial perfusion acquisition. Images were reconstructed using the standard clinical department protocol, and were analyzed by axial and lateral count profiles and polar distributions. The lateral profile showed that contrast between the lesion region and background in Cardio MD camera is higher (62.2%) than the in the CZT camera (42.5%). The axial profile showed a higher contrast (37.0%) in the CZT camera compared to Cardio MD (31.9%). CZT showed a higher contrast between background and maximum activity point along the line (68.2%) than in the Cardio MD (57.5%). Performing the maximum region relative count and the lesion area analysis, it was verified that contrast between these regions are 31.2% and 25.5% to CZT and Cardio MD, respectively. The results showed the cold myocardium lesion detectability is enhanced in the CZT camera. The polar map in the CZT camera displays a better uniformity between the segments’ counting, which means the lesion identification is clearer than in the Cardio MD camera, where the distribution is diffuse and the lesion is unclear. In conclusion, the physical performance of CZT camera is higher than conventional camera, but further studies are required to evaluate other parameters, such as spatial resolution, sensitivity and contrast-to-noise ratio.

Thus, by applying our combination technique to a well-characterized surgically induced rat hindlimb OA model, we may able to provide further insight into the role of the joint’s vascular supply as OA initiates and progresses.
The x-ray performance of the CMOS APS detector is evaluated based on experimentally measured pre-sampling modulation transfer function (pMTF), normalized noise power spectrum (NNPS) and signal-to-noise ratio (SNR). Image simulation is performed modelling the detector characteristics and the x-ray source (Xcomp5r) to estimate optimal dual energy conditions. Breast phantoms are carefully prepared to simulate the properties of real breast tissue and images are acquired using a tungsten anode x-ray source. Inside the phantom, a 2 mm diameter tube, representing the minimum tumor sizes developing angiogenesis, is placed for the injection of the different contrast media concentrations. The mean glandular dose (MGD) is evaluated and kept as low as possible to achieve sufficient image quality. The influence of scatter radiation on DE images is investigated and artefacts are reduced using a scatter-correction algorithm.

The optimum image combination is found to be at 48 kVp for both low- and high-energy x-ray beams with 0.2 mm tin and 0.3 mm copper filtration, respectively. This combination reduces the irradiation time and consequently minimizes patient motion artefacts and radiation dose. For seven image pairs, the total MGD is 1.4 mGy, which does not exceed the equivalent from a typical mammogram. Good agreement is found between the experimental and simulated results (i.e. 0.5% difference), showing that the image simulation tool is accurate to optimize a larger number of parameters and their combinations for good image quality. It is shown that the scatter-correction algorithm yields an improvement of 24% in determining iodine projected thickness, yielding an overall accuracy of the DE CEDM and CMOS APS combination within about 3% compared to the actual iodine projected thickness.

Results show that the iodine projected thickness can be effectively measured from iodinated images, and other applications, such as the measurement of contrast medium kinetics, are expectable. The performance of CMOS APS x-ray detector is within clinically acceptable accuracy and comparable with state-of-the-art technology reported in literature. This indicates that the proposed technology can be successfully combined with the DE CEDM technique for detection of early breast cancer.

**SP035.3 - Apodized-Aperture Pixel Design of an X-Ray Detector with Enhanced High-Frequency DQE and Reduced Noise Aliasing**

**Author(s):** Elina Ismailova1, Ian A. Cunningham2

1Medical Biophysics, University of Western Ontario, London/CANADA, 2Medical Biophysics, University of Western Ontario, London/ON/CANADA

The detective quantum efficiency (DQE) is a characteristic of an imaging system representing its imaging performance relative to an ideal imaging system. While high DQE values are necessary to maximize image quality using low x-ray exposures, typical DQE values are ~0.7 at low spatial frequencies and ~0.3 or less at high frequencies. We describe a CMOS/selenium-based detector using an apodized-aperture pixel (AAP) design that could achieve a new-uniform DQE over all spatial frequencies for mammographic applications. The method uses very small physical sensor elements on the CMOS sensor to synthesis larger image pixels using a novel filter design. A numerical method of optimizing the filter shape to minimize noise aliasing and maximize the DQE is described. A cascaded-systems analysis shows the limiting high-frequency DQE value can be increased from 0.3 to 0.7. The AAP approach is validated on a CMOS/CSi-based laboratory detector where the limiting DQE is increased from 0.2 to 0.4.

**SP035.4 - Geant4 Simulations of Scintillation Light Collection and Extraction in PET/CT Detectors**

**Author(s):** Francis Loignon-Houle1, Catherine M. Pepin1, Serge Charlebois2, Roger Lecomte1

1Nuclear Medicine And Radiobiology, Université de Sherbrooke, Sherbrooke/QC/CANADA, 2Electrical And Computer Engineering, Université de Sherbrooke, Sherbrooke/QC/CANADA

**Introduction**

Scintillation detectors are made of scintillation crystals coupled to photodetectors (photodiode, photomultiplier tube, SiPM, etc.). The performance of these detectors (energy and timing resolution, detection threshold, etc.) strongly depends on the collection and extraction of scintillation light from the crystal to the photodetector. To ensure high spatial resolution and high detection efficiency, scintillators must be arranged in compact arrays with unfavorable shapes for photon transport. In typical polished scintillators (n=1.8) with a form factor length/surface > 5, up to 40% of signal is lost to absorption and trapping within the crystal and attenuation through interfaces to the photodetector. In highly pixelated arrays, this loss is compounded with crosstalk effects, squandering valuable signal to adjacent pixels. The purpose of this study is to uncover processes responsible for light losses in scintillator arrays and investigate ways...
of enhancing light transport and extraction from pixelated crystals.

Materials and Methods

The Monte Carlo software Geant4 was used to simulate 511-keV annihilation photon interactions occurring in parallelepiped Lu1.9Y0.1SiO5 (LYSO) scintillators and to track the propagation of the produced scintillation photons. 4×8 crystal arrays made of 12-mm high pixels at a pitch of 1.2 mm were simulated. All crystal surfaces were defined as polished with reflectors (3M-ESR or silver foil) bonded to the lateral faces using an optical adhesive (n=1.5). Each pixel was covered with a diffuse reflector on one end (Lumirror) and read out from the other end by a surface emulating an avalanche photodiode (APD) with quantum efficiency of ~65% @ 420 nm.

Results and Discussion

Simulations revealed four main contributions to crosstalk between scintillators. First, energetic primary electrons generated near pixel lateral surfaces may escape to adjacent crystals, thus losing a fraction of the initial 511-keV energy. Since the maximum free path of 511-keV photoelectrons is limited to ~100 µm, this effect was found to be significant for interactions occurring within ~75 µm from the surface (up to 30% signal loss). Second, the 3M-ESR reflectivity severely drops from 98% down to 20% below 400 nm. Signal loss due to photons transmitted through the reflector was estimated to ~10%. This was found to be avoided with metallic reflectors. Third, the manufacturing technique used to assemble scintillator arrays is responsible for some optical leakage at the edges of pixels, resulting in asymmetric optical crosstalk amounting to 3%. Finally, scintillation photon propagation within the optical coupling layer was also found to spread the signal to adjacent crystals.

Scintillation photons escaping through the readout window have to spread across multiple interfaces (optical coupling, Si3N4) before reaching the photodetector sensitive area. Simulations reveal a strong dependence of the transmitted light fraction on angular distribution and wavelength of photons reaching each surface. Since most photons impinge on interfaces far from normal incidence, improvements in extracting these photons are feasible by adjusting the thickness and refractive index of the multiple interface layers.

Progress in scintillation light transport and extraction can potentially be achieved by optimizing all factors identified in this simulation study.

Several performance characteristics were measured as a function of bias voltage for a set of 10 prototype modules: dark current ($I_D$), relative APD gain, noise threshold (converted into keV for 200 cps without source), gain spread (maximum/minimum photopake position), energy resolution ($\Delta E$) and intrinsic time resolution ($\Delta T$). $I_D$ and APD gain measurements were performed up to breakdown voltage to determine the APD operating range. Other measurements were performed using a LabPET™ multi-channel digital data acquisition system (180 ns peaking time, preamplifier gain=8.4 mV/fC). To estimate the noise level, gain spread and $\Delta E$, a two-minute measurement was acquired with a $^{68}$Ge source (511 keV) in front of the array, followed by a 30-second background measurement without source to subtract the $^{176}$Lu natural radioactivity present in the LYSO. $\Delta T$ measurements were taken in reference to a timing probe consisting of a $^{18}$F-doped liquid scintillation/PMT detector. Results were obtained for bias values from 225 V to a maximum bias where at least 10 channels saturated the electronics.

Results

$I_D$, relative APD gain, and $\Delta T$ curves were obtained as a function of bias for all pixels. At the optimum operating bias determined from $\Delta T$ measurements, the average $I_D$, noise, gain spread, $\Delta E$ and $\Delta T$ results are respectively 18±8 nA, 39±21 keV, 3.2±1, 22±2% and 3.7±0.3 ns (with an energy threshold of 400 keV).

Conclusion

These results confirm the suitable electronic and physical performance of the detector for annihilation radiation detection. Further investigations are in progress to evaluate the imaging performance of the module for PET.

Figure 1. Energy spectra and resolution ($\Delta E$) for a typical LabPETII.5 module. The ER was measured with a $^{68}$Ge source (511 keV). The average $\Delta E$ is 22 ± 1%. The average noise threshold is 31 ± 7 keV.
SP035.6 - An alternate mathematical modeling of image formation, and framework for performance analysis of positioning algorithms in the scintillation camera

Author(s): Soheil Hosseini, Mohammad Hossein Farahani, Mohammad Reza Ay
Research Center For Molecular And Cellular Imaging, Tehran University of Medical Sciences, Tehran/IRAN

Introduction: Substantive amount of work has been done in modeling the scintillation camera system processes including positioning and image formation. This study presents an alternate mathematical modeling and subsequently framework for performance analysis of different positioning algorithms, followed by experimentation with and comparative study of several of the system parameters.

Methods: Making the assumption that a scintillation occurring in the gamma camera will result in a deterministic number of photons (proportional only to the solid angle at which it sees the detector array), the detector array counts will be found to follow the multinomial distribution with underlying probabilities determined purely through geometrical analysis. The statistical characterizations of mean, variance, and covariance of the counts will therefore be known from statistics. Anger arithmetics being presentable in terms of matrix operations on the counts vector, the mean vector and covariance matrix of the positioning output will therefore be explicitly expressible in terms of statistical characterizations of count values. Maps can moreover be constructed of displacement and blurring intensity corresponding to each point on the detector, characterizing its linearity and resolution performance. This constitutes a framework for performance analysis of different positioning algorithms. In Section I, the model is used to produce comparisons concerning photomultiplier tube (PMT) shape (square-circular-hexagonal), size, non-uniform response, and gain. In Section II, the framework has been used to analyze the performance of two more complex positioning arithmetics, involving nonlinear conditioning and exploitation of row and column sums; to that end, a new matrix formulation of the positioning output is first developed, and statistical characterization of the output are then derived using relations for moments of functions of random vectors. In Section III, the model is extended to include the complete system, including realistic versions of source, collimator and crystal, and maps are constructed for the sample case where the crystal has non-zero thickness.

Results: Figure 1 shows the case where the PMT shape and (equivalent of) size have been studied. Similar figures are created for other parameters.

Discussion: The model is evaluated against Monte Carlo simulation in several scenarios and is found to perfectly match down to any significant digit. This model can be used for in-depth study and analysis of the scintillation camera.

Figure 1: *TOP* Scatter maps showing the positioning output for uniform grid inputs. *BOTTOM* Resolution maps showing the blurring intensity corresponding to each position. In *A* PMT, *B* square PMT, *C* hexagon PMT, and *D* square PMT with source at 3/4 the default value. (A) square replaced by hexagon of equal side-to-side value. (C) hexagon replaced by the inscribing circle, and (D) square moved to 3/4 the default value. Only one quarter of the 8 x 8 detector array and side edges not included are displayed.

SP036 - Treatment Planning - Motion and Robustness

SP036.1 - Robust optimization with independent beams produces robustly matched fields for intensity-modulated proton therapy treatments

Author(s): Albin Fredriksen
Department Of Research, RaySearch Laboratories, Stockholm/SWEDEN

Background

Intensity-modulated proton therapy of the craniospinal axis typically involves matched posterior spinal fields in order to cover the spinal cord. Setup errors separating or bringing the matched fields together can cause respectively under- and overdosage at the field junction. Wedge-shaped matched beam doses, which slowly increase from zero to the prescribed dose, reduce this risk. Beam dose wedges can be achieved by treatment planning using multiple auxiliary planning structures, but such a manual process is often time-consuming. The aim of this work is to give proof-of-concept of how the creation of beam dose wedges can be automated by the use of robust optimization.

Methods

The robust optimization of the RayStation treatment planning system (RaySearch Laboratories, Stockholm, Sweden) was augmented with the ability to let setup uncertainty affect the beams independently. RayStation’s robust optimization uses dose distributions for multiple scenarios and aims to minimize the objective value under the worst case scenario. When the setup uncertainty affects the beams independently, a scenario is constituted of a specific setup error for each individual beam. For example, if two beams are used, then the total dose distribution under a given scenario may be the sum of the beam doses resulting when beam 1 is shifted superiorly and beam 2 is shifting inferiorly relative to their isocenters.

Results

Robust optimization with beams independently affected by setup uncertainty was applied to intensity-modulated proton therapy treatment planning for a craniospinal case using two parallel-opposed lateral cranial fields and two matched posterior spinal fields. The independent beam setup uncertainty was set to ±5 mm along the superoinferior axis. The optimization problem included the planning target volume and the external region without any auxiliary structures. Figure 1 shows line doses of the optimized plan over the spinal field junction. The optimization has resulted in clear beam dose wedges. The nominal total dose is slightly above the prescription of 20 Gy in order to ensure that the total dose resulting when the beams are separated is at the prescription. This provides proof-of-concept that robust optimization is a viable tool for creating robustly matched fields.
Purpose: Previously, we utilized deformable image registration (DIR) to optimize planning target volume (PTV) margins in lung cancer image-guided radiation therapy (IGRT). In this study, we have developed a method using DIR to assess the tolerance of rotational error for different image matching strategies.

Methods and Materials: 132 cone-beam computed tomography (kV CBCT) images of 8 lung cancer patients were used. Images simulating perfect set-up were created by registering each planning CT image with a CBCT image at each fraction with translations and rotations enabled. These images were rotated in all combinations of the x-, y-, and z-directions (pitch, yaw, roll) by 1, 3, 5, and 6 degrees around the centre of the spinal cord. Rotated CT images were translated to match the CBCT data nearby the spinal cord/carina or internal target volume (ITV) to obtain a simulated couch correction. Deformable image registration was used to automatically position the planning ITV on each final CBCT. ITV coverage was quantified as the percentage of the ITV surface that fell within generated PTVs.

Results: Each fraction comprised 26 rotation simulations per rotation magnitude, so a total of 3432 simulated images were analyzed per degree rotation. To achieve perfect setup, mean rotations (± standard deviation) of 1.3 ± 1.0, 1.1 ± 0.9, and 0.6 ± 0.6 degrees about the left-right (LR), anterior-posterior (AP), and superior-inferior (SI) axes were necessary. For our currently employed 6 LR, 6 AP, 10 SI mm PTV margin with cord/carina matching the mean ITV surface coverage was 99.1 ± 3.8, 98.7 ± 4.3, 96.6 ± 6.0, and 94.5 ± 7.9% for 1, 3, 5, and 6 degrees of rotation, respectively. Coverage improvement was seen when matching ITV. Alternatively, Table 1 shows the percentage of fractions where at least 99% of the ITV was within the PTV for different PTV margins and image matching strategies.

Conclusions: We used deformable image registration to evaluate the effect of rotational error in lung IGRT. Our results show that rotational errors of 3 to 5 degrees have significant effect on target coverage in IGRT protocols where couch corrections are employed to match spinal cord/carina or ITV. These results represent a worst case scenario where the patient is misregistered by the given rotation about at least one axis for all fractions. Future analyses will introduce rotations based on their probability of occurring during a treatment course as measured from previously acquired patient data.

SP036.3 - Robustness Assessment of a Novel 4D Optimization Approach for Lung Cancer Radiotherapy

Purpose: Respiratory motion is one of the main challenges in treatment of lung tumours with radiation therapy. A novel approach was to develop IMRT treatment plans, which compensate for respiratory motion and its variations, by combining intensity maps from plans optimized on the “worst case” motion variation scenarios. The objective of this work was to test this worst case planning method on both simulated and patient respiratory motion variations.

Methodology: A 4D optimization approach was implemented using the KonRad inverse planning system. Two approaches to combining the 4D optimized intensity maps were investigated: the first approach takes the average of the two intensity maps and the second approach takes the maximum intensity of the two intensity maps. The robustness of these worst case plans was compared with ITV based plans and with 4D plans optimized for the nominal motion only on three different respiratory motion variation scenarios. Study 1 investigated the robustness to simulated amplitude variations. Study 2 investigated the robustness to respiratory motion variations measured from a healthy volunteer who was asked to breathe irregularly. Study 3 investigated the robustness to motion variations of a NSCLC patient. Plans were deemed robust if they met a set of pre-defined clinical criteria for all motion variation scenarios in a given study.

Results: The average intensity worst case method was robust to motion variations in Study 3 only, except that the target volume was slightly over-dosed for the nominal motion case (64.92 Gy). The average intensity approach was not robust to motion variations in Study 1 and 2, which we attribute to the larger variation which occurred in those studies compared to the patient case. The maximum intensity worst case method, the ITV plans and the nominal 4D plans
were not robust to any of the motion variations that were tested for all three studies.

**SP036.4 - The role of VMAT interplay effects for liver stereotactic body radiation therapy**

**Author(s):** Gillian Eccleston, Greg Pierce

1Department Of Radiation Therapy, Tom Baker Cancer Centre, Calgary/CANADA, 2Department Of Medical Physics, Tom Baker Cancer Centre, Calgary/CANADA

Stereotactic body radiation therapy (SBRT) is beneficial in the treatment of solid liver cancers as it safely delivers an ablative tumor dose. Volumetric modulated arc therapy (VMAT) is an ideal modality for hypofractionated treatment regimes such as SBRT as it can efficiently deliver a conformal dose. However, treatment accuracy becomes compromised for liver tumors due to their inherent respiratory motion. Clinicians have raised concerns when treating moving targets with VMAT because the tumor motion relative to the dynamically moving MLCs degrades the plan quality; a phenomenon termed interplay. The purpose of this study is to examine if the amount of beam modulation and breathing cycle length elicits interplay effects that influence plan quality for liver SBRT treated with VMAT.

VMAT treatment plans with varying degrees of modulation were constructed using Eclipse treatment planning software, version 11.0 (Varian Medical Systems, Palo Alto, CA). Respiratory motion was modeled using an in house program that shifted the MLC leaves in each plan to simulate the motion of the GTV from the point of view of the radiation beam. IMRT modulation factors (MFs) ranged from 1.5 to 3.5 and respiratory cycle lengths of 3, 5, 10 and 20 seconds were simulated for all plans.

Minor interplay effects were observed and deemed clinically negligible: the 95% dose coverage of the target was not compromised. A slight degradation in the plan quality (size of 95% isodose) was detected and worsened with longer respiratory cycle lengths and low MFs (Fig. 1). This is attributed to the variation in gantry speed that was coupled to the MF. For high MFs (slower gantry speed), more time was available for the tumor motion to average out during each control point and as a result reducing interplay.

We concluded in this limited phantom study that treatment plan quality of liver SBRT is degraded the least by plans with high modulation factors. Plan fidelity was maintained via few partial arcs (to obtain a slow gantry speed) and adequate PTV margins that accounted for respiration.

**Conclusions:** A novel approach to create robust IMRT plans has been tested and found to be robust to most patient respiratory motion variations. Further evaluation over a wide range of tumour sizes, motion amplitudes and variability is required to determine the clinical applicability of the worst case planning method.

**SP036.5 - Interplay of MLC, gantry and respiratory motion during DCAT delivery**

**Author(s):** Tanya Kairn, Joanne Mitchell, Scott Crowe, Jamie Trapp

1Physics, Genesis CancerCare Queensland, Auchenflower/AUSTRA-LIA, 2Radiation Oncology, Royal Brisbane and Women’s Hospital, Herston/QLD/AUSTRALIA, 3Science And Engineering Faculty, Queensland University of Technology, Brisbane/AUSTRALIA

This study investigated the possible interplay effects arising from the treatment of moving targets using the dynamic conformal arc therapy (DCAT) technique. Interplay effects are known to arise from the treatment of moving anatomy with dynamic wedges and intensity modulated radiotherapy (IMRT) beams. By contrast, volumetric modulated arc therapy (VMAT) treatment beams are currently regarded as largely immune to the effects of motion interplay. This difference potentially arises from the behaviour of multi-leaf collimator (MLC) leaves during IMRT and VMAT delivery, with MLC leaves that moving from one side of each beam to the other during IMRT delivery and MLC leaves frequently change direction throughout VMAT beam delivery. DCAT treatments of lateral targets, including the peripheral lung, often require the treatment isocenter to be displaced medially to avoid collisions between gantry and couch. In these circumstances, the MLC leaf motions in DCAT beams become similar to MLC motions in IMRT beams, moving in one direction from one side of the beam to the other. This situation leads to the concern that DCAT treatments might be more susceptible to motion interplay effects than an assumed similarity to VMAT treatments would suggest.

To investigate this issue, dose from a modulated test beam was measured, with and without phantom motion and with and without a 30° arc rotation, using a diode array placed on a sinusoidally moving platform. Measurements were repeated at five different collimator angles (0, 22.5, 45, 67.5 and 90°), at two different dose rates (300 and 600 MU/min), allowing the relative effects of leaf direction and leaf speed to be evaluated. When in use, the motion platform provided regular, longitudinal (superior-inferior), sinusoidal motion, with a 40 mm peak-to-peak amplitude and a 4 s period.

Results showed that the phantom’s respiratory motion produced blurring of the dose penumbrae and consequent reduction of the area receiving high-doses, as well as dose oscillations throughout the high-dose region, which became more obvious as the MLC motion was aligned with the phantom motion direction. The delivery of the modulated beams as 30° arcs increased the penumbral dose blurring, without reducing the appearance of dose oscillations across the phantom. The dose oscillations arising from interplay...
between phantom and MLC motion were found to increase in magnitude when the dose rate was increased from 300 MU/min to 600 MU/min, effectively halving the time taken to deliver each beam.

These results suggest that DCAT treatment beams may be affected by the interplay of MLC motion and patient respiratory motion, to a similar degree as static gantry IMRT treatment beams, rather than being similar to VMAT beams.

For DCAT beams, like IMRT beams, the negative effects of motion interplay may be minimized by aligning the collimator as close to perpendicular to the dominant direction of respiratory motion as possible, by decreasing the dose rate and thereby increasing the total delivery time of each beam, and by including appropriate margins on treatment targets so that dose blurring at the edges of the beam does not compromise tumour control.

**SP036.6 - Impact of deep inspiration breath hold (DIBH) in lymphoma’s radiation therapy treatment**

**Author(s):** Daniel Venencia, Jorge Torres, Cristina Pfaff, Carola Sanchez, Jonathan Pacheco, Lucas Caussa, Edgardo Garrigó

**Fisica Medica, Instituto de Radioterapia - Fundacion Marie Curie, Cordoba/ARGENTINA**

**Purpose:** Lymphoma treatments usually require radiation therapy of mediastinum and supraclavicular lymph nodes. Planning target volume (PTV) involves several organs at risk (OAR) such as lungs, heart and esophagus. The percentage of irradiated lung depends on the PTV and total lung volume. Deep inspiration breath hold (DIBH) increase the lung volume. The objective of this work was to evaluate the impact of DIBH in the treatment of lymphoma with radiation therapy.

**Methods and Materials:** A virtual treatment simulation was performed acquiring two computed tomography (CT) image series of the patient; the first one during DIBH and the second one with free breathing. Fiducials were placed on the patient’s anterior torso surface for CT image acquisition and then used for IGRT localization. CT images were exported to treatment planning system (TPS) iPlan v4.5.3 (BrainLAB). PTV and OAR were segmented in the DIBH CT series. Treatment plans were generated using sIMRT or IMRT treatment technique with a 6MV photon beam produced by a Novalis TX linear accelerator equipped with ExacTrac IGRT system with gating capability (BrainLAB). Using iPlan RT Adaptive tool, free breathing’s segmentation and plans were generated. Four patients were analyzed (3 sIMRT and one IMRT). All plans were normalized to have the same D95% at the PTVs. Comparison between lung volumes, dose volume histogram for PTV and OAR and monitor unit (MU) were done between DIBH and free breathing plans.

**Results:** DIBH lung volume increased in average 1997.7cc [1458.7, 2785.7]. Lung DVH comparison between DIBH and free breathing exhibits a decrease of 6.2% [5, 8.8] in V6, 5.5% [4.6, 7.7] in V10, 4.8% [3.1, 8.4] in V20 and 1.4% [-0.9, 3.7] in V30. The heart showed a mean dose reduction by 2.4Gy [-0.5, 8.7] and V10 by 8.6% [3.3, 33.0]. The esophagus did not show any significant dose variations. DIBH and free breathing plans did not show any differences in MU.

**Conclusion:** Treatment plans for mediastinal lymphoma planned on DIBH showed a dose reduction in lungs and heart. There is no change in the esophagus dose and MU used. Clinical impact of lung and heart dose reduction must by analyze.

**Conclusions:** The robust optimization method can improve cardiac sparing in left-sided breast cancer IMRT, and it can potentially reduce the number of patients who need breath-hold treatments.
Conclusion

Real-time automatic marker position verification during VMAT using the MIR system is capable of detecting shifts in both static and dynamic targets, permitting reduced PTV margins for SBRT treatment with a high per-fraction dose. Automatic treatment interruption in the case of sudden excessive shifts can increase both treatment quality and treatment safety.
SP037 - Dosimetry in Nuclear Medicine

SP037.1 - Comparative Evaluation of Radiation Dose Rates in Cancer Thyroid Patients Treated with Variable Doses of Radioiodine

Author(s): Ajai Kumar Shukla, Dheeraj K. Tewari
Nuclear Medicine, SGPGIMS, Lucknow/INDIA

Cancer Thyroid patients after near total thyroidectomy are treated at our centre for radioiodine ablation using variable doses of radioiodine ranging from 3700 MBq to 7700 MBq. Initially the regulatory agency had fixed the discharge limits of 400 MBq at a distance of one meter from the patient and it usually involved a minimum isolation of about three days to decline the activity levels in patients to acceptable limits. However recently this discharge limit has now been increased to 1100 MBq and in order to see the effect of this change on the pattern of radiation levels and also on the time of discharge, the present study was undertaken on a total of 27 patients treated with doses of radiiodine I-131 ranging from 3700 MBq to 7400 MBq.

The radiation levels in uSv/hr at one meter in cancer thyroid patients (n=27) were observed to be below 50 uSv/hr on the second day itself which corresponds to about 1100 MBq residual activity. However in patients with metastatic lesions with avid concentration of I-131, the levels could decline below 50 uSv/hr only after three to four days after administration of I-131. The prolonged period taken in decline of the activity was also attributable to the fact that relatively larger amounts of activities upto 5550 MBq and in few patients 7700 MBq were administered. Prior to the change of the discharge limits the levels were used to take in some cases as more than seven days particularly in patients with metastatic lesions and administered with larger activities of the order of 5500 MBq to 7700 MBq. The prolonged isolation causes psychological trauma in some patients and therefore it was observed to be a big relief to the patients to have increased discharge limits which did not cause any significant safety related issues apart from treating more number of patients within the available infrastructure and number of isolation rooms. In addition it also enabled greater flexibility of dosing the patients with advanced disease conditions thereby reducing the overall cost of treatment.

It could be yet another school of thought to consider fractionation of doses of I-131 in those cases which needed more than seven days of isolation to prevent or minimize the risk of patient landing into extreme level of isolational stress.

SP037.2 - Estimation of the influence of other organs of the body in the determination of the gamma fraction energy emitted by iodine 131 deposited within the thyroid gland

Author(s): Abderrahim Betka, Abdelouahab Bentabet, Ahmed Azebouche, Nourdine Feneiche, Adouda Adjiri
1setif university, setif/ALGERIA, 2BordjBouariaridj université, Algeria, BordjBouariaridj/ALGERIA, 3centre de recherche nucleaire alger, Alger/ALGERIA, 4IRTES-LERMPS/FR FCLAB, UTBM, Belfort, France, Belfort/FRANCE

When treating hyperthyroidism using Iodine 131 and to facilitate and accelerate the computation time in the determination of internal dose within the thyroid gland, the shape, composition and volume of the thyroid tissue in this case is the only important factor to take into account.

This study aims to determine the fraction of energy of the gamma emission of the radioactive isotope Iodine 131 in the thyroid gland and the effect of the individual organs constituting the human body with the exception of the thyroid gland by using the geometry and material composition of each organ.

To determine the influence of the entire body, and hence its different constituting organs, on the calculation of the fraction of the gamma energy absorbed by the thyroid gland during the treatment of hyperthyroidism using iodine-131, we have performed simulations using the Monte Carlo Penelope code in the following two situations:

- Simulation of the entire body by a mathematical anthropomorphic phantom with simple geometric shapes and for this we used the example included in the Penelope code (male.geo file).
- The second situation involves simulating the thyroid gland alone.

Comparison of the results obtained by simulating the thyroid gland alone to those obtained by simulating the whole body shows a difference of 3% on average. The error in determining the dose by simulating only the geometry of the thyroid gland without involving the geometry of other organs of the body is estimated to 3%.

SP037.3 - Personalized compartmental biokinetic modelling and internal dosimetry of two novel radiopharmaceuticals

Author(s): Alexandra Zvereva, Wei B. Li, Nina Petoussi-Henss, Helmut Schlattl, Uwe Oeh, Maria Zankl, Stephan Nekolla, Christoph Hoeschen, Katia Parodi, Markus Schwaiger
1Research Unit Medical Radiation Physics And Diagnostics, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg/GERMANY, 2Department Of Nuclear Medicine, Klinikum rechts der Isar Technische Universität München, Munich/GERMANY, 3Experimental Physics – Medical Physics, Ludwig Maximilians University (LMU) Munich, Garching/GERMANY

Purpose The objective of this work is to develop personalized compartmental biokinetic models for two novel radiopharmaceuticals BAY85-8050 [1] and BAY94-9392 [2] to predict their distribution in the human body and associated patient-specific organ doses. We also aim to separately consider activities in organ parenchyma and blood in the modelling and dosimetry.

Methods The models are constructed based on clinical PET/CT images, blood and urine samples of 10 healthy volunteers [1,2]. Following an identifiability analysis of the developed models, model parameters were estimated using the commercial program SAAMII. Organ doses were calculated in accordance to the MIRD/ICRP formalism using specific absorbed fractions for photons and electrons previously simulated in the ICRP male and female reference adult computational phantoms.

Results The developed compartmental biokinetic model structure and the subset of the resulting biokinetic model predictions for BAY94-9392 are presented in Figs. 1 and 2, respectively. The corresponding figures for BAY85-8050 are not displayed here. The results showed a considerable inter-individual variability between the volunteers with effective dose coefficients of 0.016–0.018 mSv/MBq (BAY85-8050) and 0.011–0.018 mSv/MBq (BAY94-9392). We compared the personalized organ doses for two cases: (a) activities in organ parenchyma and in blood are separately modelled; (b) aggregate activities in perfused organs. For most organs the doses in case (a) were higher. Consequently, the average effective dose coefficients increased by 8.3% and 8.9% in case (a) for BAY85-8050 and BAY94-9392, respectively. Additionally, a strong influence of bladder-voiding intervals on the bladder-wall doses was demonstrated.

Conclusion The developed models can be used to estimate distributions and dose levels of two novel radiopharmaceuticals. The con-
siderable inter-individual variability helps to understand the intrinsic uncertainties when reference models are applied to individuals and justifies the advantage of personalized modelling approaches.

Clinical PET/CT centers due to high gamma energy of F18 using in 18F-FDG PET studies. The aim of this study was to evaluate the staff radiation dose in PET/CT department in Masih Daneshvari hospital.

Material and Method: during complete PET/CT imaging steps (from syringe filling to patient departure) the staff radiation dose was investigated with thermoluminescent dosimeter (TLD). The Hp(3) used for doses to the lens of the eyes and Hp(10) for doses to the whole body and Hp(0.07) for doses to the other part. For increasing the measurement accuracy, three chips of TLD used in each point of measurement. Result: the staff radiation dose were measured for work load of 53 adult patients who receive 374.28±100.30 MBq (range 127-540 MBq) 18F-FDG activity. The mean±SD total effective doses per unit of activity received by dispensing staff (n=3), imaging staff (n=5) and injection staff (n=2) were 4×10⁻⁴±5.77×10⁻⁵, 8×10⁻⁴±1×10⁻⁴ and 1×10⁻³±1×10⁻¹ µSv/MBq and received dose in eyes were 1.39×10⁻⁶±5.77×10⁻⁶, 0.87×10⁻⁶±1×10⁻⁴ and 3×10⁻⁴±1×10⁻¹ µSv/MBq as measured with TLD respectively. In this study, the finger radiation dose were higher for injection staff (7×10⁻⁶±1×10⁻¹ µSv/MBq) versus other radiation workers.

Conclusion: staff sensitive organs such as lens of eyes; thyroid and breast were received low dose in our PET/CT and cyclotron Centre. It is observed that the received radiation dose to radiation workers were below the dose limits recommended by the ICRP for all staff working in PET/CT department. This study confirmed that staff’s radiation doses in our PET/CT center were lower than those recommended by the ICRP guideline which can explain using semi-automatic injector, patient video monitoring and strong shielding performed in our center.

SP037.5 - Renewing the radiopharmaceutical accuracy check service for Canadian dose calibrators

Author(s): Raphael Galea, Khalid Gameil, Malcolm R. McEwen

Measurement Science And Standards, National Research Council, Ottawa/ON/CANADA

For a ten year period from 1986-1996, a small fraction of the Canadian nuclear medicine community participated in a service offered by the National Research Council (NRC) to check the accuracy of administered doses of radiopharmaceuticals. Similar programs exist in many countries and are of particular importance given the advent of new sources of medical isotope production anticipated to begin with the shutdown of the NRU medical isotope production in 2016. This service depends on the Secondary Standard Ionization Chambers Systems (SSIRCS) at NRC which is composed of a TPA and an NPL ion chamber coupled with an electrometer. These chambers were calibrated using radionuclidic artifacts standardized by primary methods.

These chambers have been in operation for several decades but were not operated for several years from 2001-2008 when the radionuclide metrology program ceased operations at NRC. A new data acquisition program (DAQ) was developed and new methods of determining the response of the ion chamber and electrometer were included to add redundancy and added assurance as to the calibration. Comparisons between the original and new DAQs were performed to provide validation to the chambers’ operation as well as continuity with measurements of radionuclidic artifacts still in the NRC inventory.

The original service involved the participant to measure the desired isotope in a syringe and 5 ml serum vial geometries in their dose calibrator and then send the sample to NRC to be measured in the SSIRCS and to permit an impurity check to be performed. In order to attract participation and simplify the process, the NRC is also offering an alternative service in which an ion chamber is sent to the facility, thus not requiring the shipment of isotopes, at the expense.

SP037.4 - TLD Measurement of Absorbed Dose of Workers in PET/CT Department

Author(s): Pardis Ghafarian¹, Sajede Zargan², Ali Shabestani Monfared², Ali Akbar Sharafii², Mehrdad Bakhshayeshkaram³, Mohammad Reza Ay⁴

¹Chronic Respiratory Diseases Research Center, National Research Institute Of Tuberculosis And Lung Diseases (Nritld), Shahid Beheshti University of Medical Sciences, tehran/IRAN, ²Department Of Medical Physics, Babol University of Medical Sciences, Babol/IRAN, ³Department Of Medical Physics, Iran University of Medical Sciences, Tehran/IRAN, ⁴Department Of Medical Physics And Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN

Introduction: Staff radiation protection is the critical concern in
of an impurity check. The NRC conducted a mock service on two commercial dose calibrator models CRC-35R and CRC-ULTRA for Tc99m resulting in serum vial calibration coefficients that were consistent with unity to 1% (1.005 ± 0.006 (k=2)). The reference value delivered with the Tc99m dose from the nuclear pharmacy was determined to be 0.977 ± 0.006 (k=2) of the calibrated activity. While this is well within the recommended guideline of 10% of the required dosage, in most countries, it is significantly different from unity at the 95% confidence interval to warrant the application of a calibration factor, or to monitor this value on a regular basis to detect potential drift due to mechanical of physical changes to the ion chamber.

This work was important to assure the Canadian nuclear medicine community of the existence, validation and improvements of the SSIRCS at NRC and to provide confidence and encouragement in the participation of this proficiency testing service.

SP037.6 - Radiation Dose Assessment of 99mTc-labeled Tetrofosmin in Patients Undergoing Rest-Stress Myocardial Perfusion Scintigraphy

Author(s): Stella Veloza1, Estrella Avila Ramirez2
1Physics, Universidad Nacional de Colombia, Bogota, D.C./COLOMBIA, 2Department Of Nuclear Medicine, DALINDE Medical Centre, Ciudad de Mexico/MEXICO

Purpose: Tetrofosmin labeled with technetium-99m (99mTc) is a myocardial imaging agent. The goal of this research is to evaluate the differences between two methods for assessing radiation dose: internal dosimetry by using a dose calculation program and an analytical model based on patient’s weight.

Materials and Methods: A biodistribution of 99mTc-Tetrofosmin as reported in the literature was used in OLINDA/EXM-1.0e to estimate patient-specific absorbed and effective radiation doses on 91 adults (33 female, 58 male) who were undergoing 99mTc-Tetrofosmin 8 mCi-rest/17 mCi-stress myocardial perfusion imaging. The dosimetry results were compared to the values calculated from scaling by patients’ weight, the effective dose for overweight patients are underestimated, more for female patients than for male patients because ICRP values correspond to an adult male. These underestimations are an important factor to consider if an approach based on differences in patient’s weight is used to adjust the amount of activity to be administered.

Results: The mean effective doses estimated by dosimetry in female patients were 3.46 mSv and 5.91 mSv at rest/stress respectively. In male patients the mean effective dose estimated by dosimetry was 2.87 mGy at rest and 4.86 mGy at stress. For male and female patients of the same weight the dosimetry shows that the women’s effective doses are about 17% higher than for men. The effective doses estimated in patients with a weight of 100 kg by the analytical method differed from those based on dosimetry up to 40% in women and 30% in men at rest and 35% in women and 25% in men at rest.

Conclusions: Even though the standard ICRP dose values are scaled by patients’ weight, the effective dose for overweight patients are underestimated, more for female patients than for male patients because ICRP values correspond to an adult male. These underestimations are an important factor to consider if an approach based on differences in patient’s weight is used to adjust the amount of activity to be administered.

SP037.8 - Biological Excretion and Half - Life of Remnant Radioactive Iodine 131I in Post Treated Hyperthyroidism Patients.

Objective: Following 131I treatment of hyperthyroidism; remnant activity is depleted by physical decay and bio-excretion. ICRP estimated 131I biological half-life as (138d-1960), (120d-1979), (80d-1989). This work assesses semi-empirical bio-excretion models and estimates biological half-life of post treated hyperthyroidism patients.

Patients and Method: 17 hyperthyroidism adult patients were treated with 131I (185-740MBq) depending on hyperthyroidism condition. Thyroid scans were possible by pinhole gamma camera; one and two months post 131I therapy utilizing remnant activity.

Semi-empirical excretion models developed were:

1. fixed amount \( \Gamma a(c/s)=\text{ln}([\text{In}/\text{Io}])*[(1-\text{exp}(-\lambda T))/\text{Io}] \)

2. fixed fraction \( \Gamma f=\text{exp}(-\lambda T)/\text{Io} \)

3. exponential \( \Gamma e=\lambda T \)

Bio-excretion/effective decay = (ln(In)/ln(Io)-Tp/Te, \( \lambda \) and \( T \) are: initial and \( n \)th day activity (c/s), decay coefficient \( \lambda =0.693/T, T=\text{half life} \) respectively, physical, biological and effective.

Results and Discussion: Sample series of thyroid scans are shown in (Fig.1):(A)\( ^{99m}\text{Tc} \) scan pre-treatment;(B)\( ^{131}\text{I} \) scan one month post-treatment, (C)\( ^{99m}\text{Tc} \) scan two month post-treatment, and (D)\( ^{99m}\text{Tc} \) scan six months post-treatment.

A semi logarithmic graph of relative \( \text{In}/\text{Io} \) versus time (d) showed linear relationship of \( ^{131}\text{I} \) remnant activity effective decay and physical decay (Fig.2), slope=0.693/TE=0.103, \( R^2=0.895 \), and slope=1, \( R^2=1 \) respectively. Accordingly, \( T \text{E}=6.73d, T_b=41.0d \). Calculated \( T_b \) average value=40.7±21.4d.
Measured bio-excretion of $^{131}$I contributes 3.5% of effective decay as compared to 96.5% for physical decay. Fixed amount model predicts ~9.3% bio-excretion; not significant with measured values. Fixed fraction and exponential models predict bio-excretion factor $=0.021$ of activity/day ($=0.25$ physical decay factor $=0.083$ of activity/day); significant with measured values.

We conclude that emitted radiation from remnant $^{131}$I will destroy thyroid functioning cells, reducing their ability to produce and excrete hormones, and hence increase biological half-life. Thyroid cells will be subjected to radiation hazards (beta and gamma) for 10 physical half-lives $=80$ days (remnant activity $=0.1\%$ of initial value). Caution is required with pregnant and breast feeding women.

**SP038 - Dosimetry of Non-Standard Fields**

**SP038.1 - Determination of small photon field quality correction factors using EBT3 radiochromic film**

*Author(s):* Ilias Billas, Hugo Bouchard  
Radiation Dosimetry, National Physical Laboratory, London/UNITED KINGDOM

With the upcoming IAEA-AAPM reference dosimetry protocol on small photon fields, quality correction factor data is needed. To determine these factors accurately, Monte Carlo methods are used but reliable experimental methods remain under investigation. Among the different detectors recommended by IAEA-AAPM for such conditions, radiochromic film remains promising with its high resolution and water-equivalence. However, current methods and film models available commercially (EBT3) focused on clinical applications do not meet the accuracy standards of reference dosimetry, contrary to previous models as shown in literature. The goal of this work is to develop a reliable approach for radiochromic film dosimetry, reaching 0.5% statistical uncertainty on relative pixel dose with EBT3 and reducing systematic errors caused by film thickness inhomogeneity.

An original multichannel method is developed based on a simple 2D model of the film response to dose and thickness and statistical analysis of the calibrated film. Gafchromic EBT3 films are irradiated with cobalt-60 beams homogenously, allowing obtaining parameters for scanner homogeneity correction, multichannel analysis and dose response calibration. Software is developed for film characterization and analysis. Dose distribution measurements are compared to reference data and an uncertainty budget is made to quantify the performance of the method in correcting systematic errors in film response. Based on the analysis, conditions to achieve 0.5% uncertainty in relative measurements are determined. Systematic errors are compared to the statistical behaviour of pixel dose.

Comparing single and multichannel methods, it is demonstrated that the proposed method reduces systematic errors significantly. The method allows uncertainties in output factors of 1.2% for single measurements and 0.4% for measurements repeated ten times. Comparisons with known dose distributions show systematic errors up to 10% with single channel analysis, while they are on average diminished by a factor up to three and well below statistical uncertainties with the multichannel method. The figure shows a comparison of the methods in measuring a $10 \times 10$ cm$^2$ cobalt-60 beam profile: a beam profile (left) and a dose map (right).

Results suggest that a controlled experimental procedure and proper analysis yield great potential for small photon field dosimetry using radiochromic film, with uncertainties in quality correction factors comparable to previous film models. It is expected that future experiments with small photon fields will validate the theoretical predictions reported herein.
The upcoming IAEA-AAPM protocol for dosimetry of small photon fields is expected to improve the calibration of such beams, benefitting patient safety and treatment outcome. As a complement to such procedures, a clear presentation of the main effects responsible for large detector correction factors is highly valuable. The physics of small fields is a rather complex subject and has not yet been treated in the literature in a conceptually sound manner. Hence, confusion over the limitations of dosimetry protocols in small fields still exists. The present study aims to provide a comprehensive explanation why dosimetry of megavoltage small photon fields can require significant quality correction factors.

Several concepts are reviewed from a theoretical point of view. The applicability of cavity theory to small fields is described, and a simpler cavity theory is proposed. The concept of charged particle equilibrium (CPE) and its impact on dosimetry is evaluated in detail. The perturbations caused by the presence of a detector are also analysed thoroughly. Four main effects are identified and related to detector characteristics: 1) the density of the cavity material, 2) the atomic properties of the cavity material, 3) the presence of extracameral components and 4) volume averaging effects. The theory is supported by a series of Monte Carlo calculations characterizing detector response to pencil photon beams.

The analysis and results presented here clarify several misconceptions in some of the existing literature on small field dosimetry. Evaluation of the four perturbation effects indicates that significant correction factors arise mainly from the interplay between lack of CPE and cavity density. New Monte Carlo results as well as key publications on the topic strongly support this conclusion. Figure 1 shows simulated detector dose response to a pencil beam under Fano’s conditions, and illustrates the interplay between lack of CPE and cavity density.

This study presents an analysis of the physics of small field dosimetry and allows in-depth clarification of the reasons for significant quality correction factors in megavoltage small photon fields. It is expected to be a valuable complement to the upcoming dosimetry protocol which mainly focuses on the technical aspects of small field dosimetry.

Figure 1. Dose response of a cylindrical cavity, 1 cm diameter, to a 1.25 MeV monoenergetic photon pencil beam, as a function of beam distance from the cavity axis. Calculations are performed using Fano calculations so that the integral of the curve is independent of the cavity density.

A new facility to support the adaptation of reference dosimetry in the presence of strong magnetic fields

Author(s): Simon Duane, James Manning, Giuseppe Schettino, Hugo Bouchard

Radiation Dosimetry, National Physical Laboratory, London/UNITED KINGDOM

Novel technology integrating MRI with the delivery of megavoltage photon radiotherapy promises unique advantages for image guidance. At MRI strengths, magnetic fields can have a significant impact on the dosimetry. To calibrate these new machines, detector dose response must be thoroughly investigated and validated data must be available. However, it remains a challenge to isolate the effect of the magnetic field on dosimeter response. While alanine is a promising nearly water-equivalent detector, its potential as a reference dosimeter in the presence of a strong magnetic field has yet to be demonstrated experimentally.

A new experimental facility, unique among standards laboratories, is set up using a dipole magnet with field strengths up to 2 T in a cobalt-60 beam (see figure). The EPR response of nine 2.4 mm alanine pellets in a 2 x 2 x 2 cm³ mini-phantom, irradiated to 20 Gy in 0 T and 2 T fields, is evaluated repeatedly to assure optimal precision. The effect of the magnetic field on absorbed dose to water is determined using a limit approach combining Monte Carlo data and the magnetic field-independence of kerma.

The uniformity of the pellet dose is consistent with expectations given the stack orientation being parallel to the magnetic field and perpendicular to the beam. Doses are averaged for inner pellets, away from the phantom edges. The dose correction in water and its type B uncertainty are estimated from existing Monte Carlo data. The correction kQB,Q0 varies from 0.9897 to 0.9978 over the pellets, with a standard deviation of 0.0030. This gives a mean quality correction factor of 0.9955 with a combined uncertainty of 0.0035 (k=2) at 2 T. This result is consistent with the alanine dose response being only slightly affected by the 2 T magnetic field. It is demonstrated alanine has the potential to serve as a reference detector for the experimental determination of magnetic field quality correction factors.

Combined with alanine/EPR dosimetry, the new experimental facility has the capability of validating Monte Carlo data of detector response in strong magnetic fields. This is expected to impact the robustness of future reference dosimetry protocols adapted for use with MRI-guided radiotherapy machines. Future work includes determining the response of alanine in a wide range of field strengths as well as the characterization of this effect on other detectors.

SP039.1 - Improved T-wave Alternans Detection in ECG Signals

**Author(s):** Guangyi Chen¹, Sridhar Krishnan¹, Vijay S. Chauhan²

¹Ryerson University, Toronto/CANADA, ²Toronto General Hospital, Toronto/CANADA

T-wave alternans (TWA) is a pattern in electrocardiogram (ECG) signals characterized by two distinct forms of T-waves appearing in alternation, at a patient’s heart rate in the range of 90 to 120 beats per minute. There exists a relation between the amount of TWA, the heart rate at which it appears, and the risk of sudden cardiac death (SCD). Therefore, it is important to develop better methods to detect TWA in ECG signals.

In this paper, we enhance an existing method for detecting TWA in ECG signals. We reduce the noise in the ECG signals adaptively by using dual-tree complex wavelet transform (DTCWT). Our method for detecting TWA is based on the Matlab code of the champion (Jubair Sieed) in the 2008 TWA challenge. We modified his Matlab code in a number of ways as shown in the full paper. We briefly describe the steps of our proposed method for detecting TWA in ECG signals here:

1) We perform moderate filtering to the input ECG signal x(t), just as the original method.
2) Apply wavelet denoising to every ECG signal adaptively. 
3) We find the R-peaks in the filtered ECG signal.
4) We calculate the T-peaks and their amplitude. 
5) We find the TWA waveform. We use the median instead of the maximum for the T-wave magnitude of each lead.
6) We calculate the T-wave magnitude of the whole ECG signal with multiple leads. 

In our experiments, we select to use the ECG signals provided by the 2008 TWA challenge, which contains one hundred multi-channel ECG records sampled at 500 Hz with 16-bit resolution over a ±32 mV ranges. We perform comparisons among our proposed method and three existing methods, developed by Jubair Sieed, Renata Simoliunine, and Mahdi Zarrini. They have posted their Matlab codes on the 2008 TWA website. We select four metrics for measuring the quality of the detected T-waves: Spearman rank correlation coefficient, Kendall rank correlation coefficient, root-mean-square-error (RMSE), and cross correlation (CC). From Table 1, it can be seen that our proposed method performs the best, compared to the three existing methods.

**SP039.2 - Electrical Left Atrial Conduction Delay with Focused Transesophageal Electrocardiography in Cardiac Resynchronization Therapy**

**Author(s):** Matthias Heinke¹, Helmut Kühnert², Tobias Heinke³, Jonas Tumapos³, Gudrun Dannberg¹

¹Electrical And Information Technology, Medical Engineering, University of Applied Sciences Offenburg, Offenburg/GERMANY, ²Department Of Internal Medicine I, University of Jena, Jena/GERMANY, ³Healthcare Sector, Siemens AG, Rudolstadt/GERMANY

Cardiac resynchronization therapy (CRT) is an established biventricular pacing therapy in heart failure patients with left bundle branch block and reduced left ventricular ejection fraction, but not all patients improved clinically as CRT responder. Purpose of the study was to evaluate electrical left atrial conduction delay (LACD) with focused transesophageal electrocardiography in CRT responder and CRT non-responder.

**Methods:** Twenty heart failure patients (age 66.6±8.2 years; 2 females, 18 males) with New York Heart Association functional class 3.0±0.3 and 174.2±40.2ms QRS duration were analysed using posterior left atrial transesophageal electrocardiography with hemispherical electrodes. Electrical LACD was measured between onset and offset of transesophageal left atrial signal before implantation of CRT devices.

**Results:** Electrical LACD could be evaluated by bipolar transesophageal left atrial electrocardiography using TO Osypka electrode in all heart failure patients with negative correlation between 54.7±18.1ms LACD and 24.9±6.4% left ventricular ejection fraction (r=-0.65, P=0.002). There were 16 CRT responders with reduction of New York Heart Association functional class from 3.0±0.2 to 2.1±0.2 (r=0.522, P=0.038) during 9.4±10.9 months CRT. There were 4 CRT non-responders with no reduction of New York Heart Association functional class from 3.0±0.4 to 2.8±0.5 (r=0.816, P=0.184) during 13.8±16.3 months CRT. Electrical LACD correlated negative with left ventricular ejection fraction between 75.25±19.17ms LACD and 20.75±6.4% left ventricular ejection fraction (r=-0.831, P=0.169).

**Conclusions:** Focused transesophageal left atrial electrocardiography can be utilized to analyse electrical LACD in heart failure patients. LACD correlated negative with left ventricular ejection fraction in CRT responders. LACD may be a useful parameter to evaluate electrical left atrial desynchronization in heart failure patients.

**SP039.3 - Electrical Interventricular to Interventricular Conduction Delay Ratio with Focused Transesophageal Electrocardiography in Cardiac Resynchronization Therapy**

**Author(s):** Matthias Heinke¹, Gudrun Dannberg², Tobias Heinke³, Bruno Ismer³, Tobias Haber³, Jonas Tumapos³, Helmut Kühnert³

¹Electrical And Information Technology, Medical Engineering, University of Applied Sciences Offenburg, Offenburg/GERMANY, ²Department Of Internal Medicine I, University of Jena, Jena/GERMANY, ³Healthcare Sector, Siemens AG, Rudolstadt/GERMANY
Cardiac resynchronization therapy (CRT) is an established class I level A biventricular pacing therapy in chronic heart failure patients with left bundle branch block and reduced left ventricular ejection fraction, but not all patients improved clinically. Purpose of the study was to evaluate electrical interatrial conduction delay (IACD) to interventricular conduction delay (IVCD) ratio with focused transesophageal left atrial and left ventricular electrocardiography.

**Methods:** Thirty eight chronic heart failure patients (age 63.4±10.2 years; 3 females, 35 males) with New York Heart Association (NYHA) functional class 3.0±0.2 and 171.7±36.17ms QRS duration were analysed using posterior left atrial and left ventricular transesophageal electrocardiography with hemispherical electrodes before CRT. Electrical IACD was measured between onset of P-wave in the surface ECG and onset of left atrial signal. Electrical IVCD was measured between onset of QRS complex in the surface ECG and onset of left ventricular signal.

**Results:** Electrical IACD and IVCD could be evaluated by transesophageal left atrial and left ventricular electrocardiography in all heart failure patients with correlation to 1.18±0.92 IACD-IVCD-ratio (r=-0.57, P<0.001; r=0.66, P<0.001). There were 32 CRT responder with reduction of NYHA class from 3.0±0.22 to 1.97±0.31 (P<0.001) during 16.5±18.9 month CRT with 75.19±33.49ms IACD, 78.91±24.73ms IVCD, 1.04±0.66 IACD-IVCD-ratio and correlation between IACD and IACD-IVCD-ratio (r=0.84, P<0.001). There were 6 CRT non-responder with no reduction of NYHA class from 3.0±0.3 to 2.9±0.5 during 14.3±13.7 month biventricular pacing, 50.0±28.26ms IVCD (P=0.014), 1.92±1.65 IACD-IVCD-ratio (P=0.029) and correlation between 67.0±24.9ms IACD and IACD-IVCD-ratio (r=0.85, P=0.031).

**Conclusions:** Focused transesophageal left atrial and left ventricular electrocardiography can be utilized to analyse electrical IACD and IVCD in heart failure patients. IACD-IVCD-ratio may be a useful parameter to evaluate electrical left cardiac desynchronization in heart failure patients.

SP039.4 - Analytical geometry based parameters for studying repolarization variability in patients with myocardial infarction

**Authors:** Muhammad A. Hasan, Sridhar Krishnan

Electrical And Computer Engineering, Ryerson University, TORONTO/ON/CANADA

Myocardial infarction (MI) is one of the leading causes of mortality throughout the world [1]. About 69,000 Canadians and 600,000 people in the United States die as a result of heart attack every year [2]. The myocardium cells of the heart are altered in ventricular repolarization after MI. Thus, studying variability in ventricular repolarization on a beat-by-beat basis has gained significant interest from clinicians and basic scientists. Indeed, the T-wave in the ECG signal refers to the ventricular repolarization and is believed to be a predictor for the risk of ventricular arrhythmias [3]. However, the beat-to-beat repolarization variability in MI patients has not been fully understood. Therefore, the purpose of this research is to study the beat-to-beat repolarization variability and to assess the predictive capabilities of geometry based parameters for studying repolarization variability in MI patients (79 patients) compared to healthy subjects (69 subjects). To study the beat-to-beat repolarization variability, we extracted some geometrical based T-wave parameters [T-wave amplitudes (h), distances between Q-wave onset to T-wave max (Q2Tmax), angles between T-wave max and T-wave end with respect to Q-wave (TmaxQTend)] as shown in Figure 1. The detailed methodology have been described in our recent article [3]. We quantified the standard deviation of the extracted parameters as a marker of repolarization variability, respectively for both MI patients and healthy subjects. Beat-to-beat repolarization variability (in all three extracted parameters) was found to be significantly higher in MI patients compared to healthy subjects. In conclusion, this research shows that the geometrical based parameters for repolarization variability may provide markers for separating MI patients and healthy subjects.

SP039.5 - Acute Mental Stress Detection via Ultra-short term HRV Analysis

**Authors:** Rossana Castaldo1, Laandro Pecchia1, Paolo Melillo2

1School Of Engineering, University of Warwick, Coventry/UNITED KINGDOM, 2Multidisciplinary Department Of Medical, Surgical And Dental Sciences, Second University of Naples, Naples/ITALY

Acute mental stress reduces working performances and it is one of the first causes of cognitive dysfunctions, cardiovascular disorders and depression. Stress detection via short-term (5 minutes) Heart Rate Variability (HRV) analysis has been widely investigated in the last years. Recent improvements in wearable sensing devices and mobile computing raised a new research question: is ultra-short (2 minutes) HRV analysis as effective as the short-term
analysis to detect mental stress? This study aimed to answer this research question.

**Methods:** Short and ultra-short HRV analysis were compared in 42 healthy subjects (age 25–38 year) undertaking the widely adopted and highly-effective Stroop Color Word Test (CWTT). HRV was extracted by ECG signals recorded during rest and stress session using a chest wearable monitoring device, the BioHarness M3 (ZephyrTech, NZ). According to previous literature on HRV and mental stress, 18 HRV measures were extracted and analyzed using validated software tools. However, among the 18 HRV measures, only those that changed significantly in the short-term were also investigated in the ultra-short term analysis. Variations in HRV measures in short and ultra-short term were compared using the statistical Wilcoxon significance test, because several measures were not normally distributed.

**Results:** The results of the current study proved that among the 18 HRV measures investigated, 10 HRV measures resulted significantly changed in the short-term analysis during mental stress. Among such 10 HRV measures, only 6 HRV measures presented a consistent behavior in the short and ultra-short registration: Mean RR, Low Frequency power (LF), Sample Entropy (Sampen), Short term and Long term fluctuation slope of Detrended fluctuation analysis (df01, df02) and Mean line length of Recurrence plot analysis (RPlmean). Particularly, Mean RR and df01 significantly increased during stress, while the other significantly decreased. In contrast, the remaining 4 HRV measures, changed significantly in the 5 min analysis but not in the 2 min analysis, although the trends were consistent. In fact, the ratio of LF and High Frequency power (HF) resulted increased during stress, while Correlation dimension (D2), Recurrence rate (REC) and Shannon Entropy (ShanEn) decreased. This can be explained by the fact that in less than 5 minutes the number of RR recorded is too low in order to observe significant changes. This can be verified enrolling more volunteers.

**Conclusion:** The current study showed that among the 18 HRV measures investigated, 10 resulted significantly changed during mental stress. However among those, only 6 changed consistently both in the short and ultra-short HRV analysis, while 4 resulted to be not significant in ultra-short term. This evidence suggested that in the shift from short to ultra-short HRV analysis, not all the features can be equally used and therefore further studies are needed to prove that HRV measures change significantly even during stress in the ultra-short term.

SP039.6 - Classification of Abdominal Fetal Electrocardiogram Recordings using Karhunen-Loève Decomposition

**Author(s):** Philip A. Warrick1, Miguel A. Altuve2
1Medical Research And Development, PeriGen Inc., Montreal/Canada, 2Facultad De Ingeniería Electrónica, Universidad Pontificia Bolivariana, Bucaramanga/COLOMBIA

Maternal abdominal ECG acquisition is a non-invasive technique not usually common in clinical practice but with a growing interest since it could provide enough information to explore the cardiovascular condition of the fetus after the 20th week of gestation. Since the maternal and fetal cardiac activities are combined in the ECG signal, several challenges have to be surmounted to obtain a useful fetal ECG signal from the maternal abdominal ECG like the overlapping observed in time and in frequency of both components and the low signal-to-noise ratio of the signal. In the present study, the maternal and fetal activities were exploited through the decomposition of maternal abdominal ECG recordings using the Karhunen-Loève (KL) transform. Then, several feature sets extracted from the KL decomposition and from the ECG signal were combined in support vector machines classifiers to detect the presence and absence of a maternal and/or a fetal QRS complex from ECG segments of 250 ms duration. Results show that a fetal QRS complex was well detected when there was not overlap with a maternal QRS (sensitivity 88.8%, specificity 97.1%) while detection diminished somewhat when overlapping was present (sensitivity 90.7%, specificity 75.9%). Detecting maternal activity using the KL decomposition was a relatively simple task; the main goal of detecting the fetal activity was effectively achieved when the fetus activity occurred in isolation, but was a more difficult task when accompanied by temporally adjacent maternal activity.

SP039.7 - Dictionary Learning Algorithms For The Application Of Ventricular Arrhythmia Classification.

**Author(s):** Imran Kalai1, Krishnanand Balasundaram2, Karthi Umapathy1
1Electrical And Computer Engineering Dept., Ryerson University, Toronto/ON/CANADA, 2Electrical And Computer Engineering Dept., Ryerson University, Toronto/CANADA

**Background:**

The classification of cardiac arrhythmias such as ventricular tachycardia (VT) and ventricular fibrillation (VF) has been an important research topic in the signal processing field due to its lethal effects. Therefore, it is important to classify arrhythmias to deliver the appropriate treatments and prevent sudden cardiac arrests. Researchers presented an automated algorithm that express non-stationary signals by decomposing them into a linear expansion of different known mathematical functions that are well localized in both time and frequency domains. A family of the mathematical functions (atoms) creates a dictionary; the choice of the dictionary plays an important role in an accurate representation. Hence, researchers developed dictionary learning algorithms to create a learned dictionary using a training data to adapt its content to the given signals such that it provides a better approximation from an over complete redundant dictionary. In this work, due to the non-stationary nature of the electrocardiogram (ECG) signals during an arrhythmic event, these existing algorithms were used to classify between VT and VF signals using the dictionary learning algorithm LC-KSVD. Nine hundred and forty four surface ECG signal segments (four seconds each) from the MIT-BIH database were used for the classification derived from twenty three VF signals and ten VT signals.

**Methodology:**

The dictionary learning algorithm that is used in this study is called label consistent K-SVD. In the LC-KSVD algorithm, a discriminative dictionary is learned for sparse coding. It uses a class label of a training data as well as it associates label information with each dictionary item to enforce discriminability in sparse codes during the dictionary learning process (same class signals has similar sparse coding). Furthermore, it uses a label consistency constraint called “discriminative sparse-code error” and combines it with the reconstruction error and the classification error to form an objective function. The optimal solution of the objective function is efficiently obtained using the K-SVD Algorithm. This algorithm learns the dictionary, discriminative coding parameters, and classifier parameters for optimal linear classifier simultaneously.

**Results and Conclusion:**

Based on our analysis using the LC-KSVD algorithm to train an over complete hybrid dictionary consisting of cosine, symlet4, daubechies4 wavelet atoms, we were able to classify the VF and VT signals with an average of accuracy of 70.8% using LDA classifier. The results were validated with four fold cross-validations.
SP040.1 - Working to live: The use of field studies and simulations to make workplaces safer

Author(s): Michele Oliver
School Of Engineering, University of Guelph, Guelph/ON/CANADA

Working to live: The use of field studies and simulations to make workplaces safer

Employers want to reduce accidents and overuse injuries amongst their workers but often they don’t possess the required tools and information so they need to turn to research for answers. From a research perspective, first you need to understand the problem and then you can design a solution that will have the greatest impact in reducing or eliminating the problem. This can be accomplished through a combination of field and laboratory studies. To illustrate this I will present results from a series of laboratory and field studies designed to assess and solve occupational problems primarily amongst operators of heavy mobile equipment.

The thought process and studies that went into the design and development of a heavy equipment dynamic armrest will be described. The armrest was designed to translate and rotate in order to mimic natural pendulation of an operator’s arm thus minimizing upper limb and neck muscle activity as they operate joystick controls.

Results from a comprehensive field study which concurrently assessed the biomechanical and physiological requirements of overhead crane cab operation in a steel mill will be discussed as will the companion study which utilized the results of the field study to set up a laboratory based simulation in order to determine if a camera based system could reduce musculoskeletal loading in the trunk, arms and neck for crane cab operators by allowing them to maintain a more neutral posture.

The final set of studies I will discuss describe the results of a series of field to lab to field methodologies developed to intelligently retrofit seats used in steel manufacturing mobile equipment in order to minimize operator exposure to whole-body vibration. When companies retrofit machines, seats are usually selected and implemented without an evaluation process based on actual machine and/or terrain specific vibration inputs to assess seat efficacy. In general, operators test and choose seats from a showroom rather than testing them in operating machines. Our research team utilized a person rated hexapod robot simulator to replicate field-based machine specific vibration to evaluate several commercially available seats to identify the best seat for the workplace application. The selected seat was successfully introduced back into the workplace resulting in reduced vibration exposure and improved worker comfort.

Finally, I will talk briefly about some of the ongoing work with our new driving and hexapod robot heavy equipment simulator facilities which bring together a multidisciplinary team of researchers from engineering, computer science and psychology.

SP040.2 - Pitch movement acceleration measures during the practice of virtual games in adolescents with Down syndrome

Author(s): Daniela Carrogi-Vianna1, Paulo B. Lopes2, Raquel Cymrot2, Jefferson J.H. Almeida3, Marcos L. Yazaki2, Silvana Maria Blascovi-Assis3

1Post Graduation In Developmental Disorders, Universidade Paulista and Universidade Presbiteriana Mackenzie, Sorocaba - São Paulo/BRAZIL, 2School Of Engineering, Universidade Presbiteriana Mackenzie, São Paulo/BRAZIL, 3Post Graduation In Developmental Disorders, Universidade Presbiteriana Mackenzie, São Paulo/BRAZIL

I. INTRODUCTION

Adolescents with Down syndrome (DS) present a range of motor difficulties. Therefore they do not specify a temporal-spatial pattern of muscle contractions, causing major difficulties to perform a task in time.

The Virtual Reality (VR) has been regularly used as a method of physical rehabilitation, which is based on the use of virtual games in order to enable the function of people with several types of disabilities.

The Nintendo® Wii™ console is the most used in the virtual rehabilitation of people with multiple disabilities.

The accelerometry has been used to establish measures of human movement, since it is an inexpensive, effective and feasible method, which has been widely used in scientific researches.

II. OBJECTIVE

Evaluating the characteristics of movement acceleration of upper limbs for adolescents with DS and adolescents with typical development, by playing bowling and golf of Nintendo® Wii™.

III. CASE STUDY AND METHOD

The study evaluated 21 adolescents diagnosed with DS (FDSG and MDSG) and 33 with typical development (FCG and MCG), of both genders (F and M), aged between 10 and 14. The data was gathered by using wireless capacitive triaxial accelerometers.

IV. RESULTS

For the data analysis, four groups were submitted to normality adherence tests, separate by gender.

A. Bowling game

In the significance level of 10%, there was adherence to the normal distribution of the maximum peaks of acceleration obtained by the four groups. The Medium acceleration per group were: FCG 70.51; MCG 70.37; FDSG 37.24; MDSG 45.33.

It was concluded that the groups presented significant statistical differences, with higher peaks of acceleration for MCG and FCG when they are compared with MDSG and FDSG.

B. Golf game

In the significance level of 10%, there was adherence to the normal distribution of the maximum peaks of acceleration, obtained by the three groups (FCG, MCG, FDSG). In the significance level of 10% there was no adherence to the Normal Distribution of the maximum peaks of acceleration for MDSG. The Medium acceleration per group were: FCG 56.80; MCG 74.80; FDSG 30.52; MDSG 45.12.

It was concluded that the groups presented significant statistical differences, with the highest peak of acceleration for the boys group, which had superior average compared to the girls group, observed in both MCG and FCG, as well as in MDSG and in FDSG.

V. CONCLUSIONS

By efficiently using the accelerometry, it was possible to evaluate...
the characteristics of the movement acceleration of the superior limbs of the population diagnosed with DS during the virtual bowling and golf games, using the Nintendo® Wii™ console. It was observed a better performance in every single evaluation for the control group, having lower acceleration in the movement of adolescents with DS. It was concluded that the use of Nintendo® Wii™ associated with the accelerometry technique may be an effective resource to evaluate movement acceleration patterns in population with DS.

**SP040.3 - Movement Training and Assessment with 3D Virtual Reality for Parkinson’s Disease Patient**

**Author(s):** Chien-An Chen1, Hsiao-Yu Lee2, Zong-Syuan Huang1, Chao-Chen Lo3, Jia-Jin Chen1, Yu-Lin Wang1, Kao-Chang Lin1

1Biomedical Engineering, National Cheng Kung University, Tainan/ TAIWAN, 2Far East University, Tainan/TAIWAN, 3Chi Mei Hospital, Tainan/TAIWAN

Balance problems such as inability to maintain stability and postural transition are common in patients with Parkinson’s Disease (PD). In clinical, visual cues are used as rehabilitation program in improving postural stability. Ball catching movement is considered a kind of suitable training program for PD patients because of its characteristics of eye-hand-foot coordination. Furthermore, studies have shown that optical flow could provide motion perceptions and improve movement performance of PD patients. The purpose of this study was to develop a 3D virtual reality (VR) training system for providing optical flow information during catching virtual balls under standing and one-step forward movements for subjects with PD. Fifteen PD participants were recruited from local medical center. The effects of optical flow on postural stability were evaluated by standing and one-step forward task using our 3D VR system providing virtual catching ball with and without optical flow. The arm-trunk movement and trunk movement were utilized as the assessment indices of balance and postural control by inertial sensors attached on waist and bilateral of wrists. Our results showed better arm-trunk coordination and higher similarity of arm symmetry with smoother movement pattern, greater trunk sway, and better postural stability index under the standing task with optical flow. Moreover, PD patients also spent substantially less duration prior to gait initiation and achieved greater inclination angle on one-step forward task. The balance training system accompanied with evaluation system demonstrated that arm-trunk control and balance on ball catching performance of PD patients could be improved with optical flow information.

**SP040.4 - Arm angle detection in egocentric video of upper extremity tasks**

**Author(s):** Jirapat Likitlersuang, José Zariffa Institute Of Biomaterials And Biomedical Engineering (ibbme), University of Toronto, Toronto/ON/CANADA

**Background:** Upper limb function is fundamental to most activities of daily living (ADL), and can be dramatically impaired after neurological injuries, such as spinal cord injury. Currently there is no viable method to assess and monitor hand function once the patient has returned to the community after rehabilitation. Our solution is to track hand use in the community by developing a computer vision (CV)-based wearable sensor using egocentric cameras, in order to capture information about a person’s level of independence and reliance on attendant care. Such a system needs to be able to differentiate object manipulations performed by the user from those performed by a caregiver, as well as the user’s right and left hands. The angle of the arm in the video is important in this classification. Here we describe and compare three methods for detecting arm angles in egocentric view. **Methods:** Following hand detection, Method I uses a Haar-like feature to compare the contents of a rectangle extending from the hand to two parallel rectangles on either side, rotating these through 360 degrees range. Method II is based on Hough line transforms and attempts to determine which of the detected lines passing though the hand correspond to the edges of the sleeve. Method III detects the contour of the sleeve based on a colour histogram obtained through a calibration step. A least squares fit is then applied to the detected sleeve to determine the angle of the arm. The three methods were tested by comparing their output to manually measured angles, in 120 frames of recorded egocentric video consisting of 4 ADLs from 3 different able-bodied subjects. **Results:** Based on absolute error, Method III was shown to have the best performance with a mean absolute error of 23.70 ± 22.89 degrees. This was followed by Method I with the mean absolute error of 34.79 ± 38.48 degrees and Method II with the mean absolute error of 68.76 ± 58.01 degrees (Fig. 1). **Conclusion:** While Method III had the smallest error, it required a calibration step to determine the colour of the sleeve, and this makes this method less practical compared to Method I, which does not require any calibration and still had a comparable error. We have demonstrated that a Haar-like feature method can easily be integrated with hand detection to determine arm angle in an egocentric CV-based wearable sensor for detecting hand usage at home.

**SP040.5 - Development of an image-based calibration technique for use with non-ideal postures in the assessment of kinematics using wearable sensors**

**Author(s):** Jan Andrysek, Monica D. Gomez Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA

**Introduction:**

Wearable sensors are emerging low-cost alternatives to expand the current gold-standard camera-based assessment of kinematics, allowing for measurements in real-life conditions and environments. MVN BIOMECH Awinda system is an example of a commercial wearable sensor system used to analyze whole body kinematics. However, to calibrate the device, an ideal upright position known as “Neutral Posture,” or “N-Pose,” must be attained. Hence, these sensors have limitations in the rehab field where muscle weakness, bone deformity, sensory loss, pain or impaired control hinders or makes it impossible to attain N-Pose. Developing a calibration technique that adjusts the model to account for actual orientation and position of body segments, versus the assumed N-Pose, will improve the estimation of kinematics. Therefore, this study aims to produce calibration parameters which will be used to adjust the "N-
Pose”. Here, Kinect sensor is used to extract body segment lengths, knee, hip and ankle angles as the calibration parameters.

**Research Objectives**

**Obj.1** Understand how non-ideal calibration postures affect the accuracy of lower body kinematics estimation.

**Obj.2** Develop an image-based calibration technique using Kinect to acquire calibration parameters.

**Methods**

**Obj.1** A pilot study was conducted to assess the accuracy of knee and ankle angles in the sagittal plane of a participant’s gait. The MVN BIOMECH Awinda system was used to measure patient’s kinematics after calibrating the system with (a) the N-Pose and two non-ideal calibration postures: (b) bent knees and (c) standing on tip-toes.

**Obj.2** The depth sensor Kinect for Windows is used to determine the position of optical markers placed on participant’s body landmarks. With this information, distance between markers is estimated and then used to find joint centers. Next, joint centers are connected to form lines that will represent the body segments, and from these segment lines angles are calculated using the dot product to find the angle between two vectors. In combination with these positions and angles (calibration parameters), sensor data collected from participant’s gait using the MVN BIOMECH’s lower body configuration are used to re-estimate gait kinematics.

**Preliminary Results**

**Obj.1** Results showed that for both cases the difference between angles obtained in (a) and (b) (40.88 degrees) and (a) and (c) (53.88 degrees) is consistent throughout the gait cycle; and the coefficients of multiple correlation [5] represent good level of similarity between (a) and (b) (0.98) and between (a) and (c) (0.93). These results show that the inaccuracy of kinematics after calibrating with non-ideal postures is mainly due to the offset between waveforms. This suggests that the proposed calibration technique for Obj. 2, which is in design stage, can provide a good solution for the calibration problem.

**Clinical Significance**

Improving the calibration process of these wearable systems to account for non-ideal postures makes them suitable for a variety of patient populations. This technique will ultimately provide clinicians and researchers with a valuable tool to analyze the kinematics in real life environments.

**SP041 - Brain Computer/Machine Interfaces**

**SP041.1 - Cross-subject and Cross-gender Emotion Classification from EEG**

**Author(s):** Jia-Yi Zhu, Wei-Long Zheng, Bao-Liang Lu

Computer Science And Engineering, Shanghai Jiao Tong University, Shanghai/CHINA

Emotion is a general definition for subjective cognition experiences, including psychological and physiological states aroused by one’s feeling, thinking, and behaviors. With the development of artificial intelligence, affective computing based on computer systems is considered to make human-machine interaction more friendly and convenient. Recently, progresses of brain-computer technology encourage researches on EEG-based emotion recognition in the field of neuroengineering. Previous studies have indicated that EEG does change with emotional states in specific patterns. To our best knowledge, however, EEG models used in the existing studies were almost subject-dependent. Thus, there is no definite conclusion on whether these patterns are universal across different subjects.

The main goals of this study are to find a subject-independent EEG model for emotion classification and examine gender differences of EEG patterns as one of the major factors affecting the performance of cross-subject models. In this paper, we use movie clips as stimuli to evoke three emotional states: positive, neutral, and negative. We adopt differential entropy as features, and apply linear dynamic system to do feature smoothing. The average in-subject classification accuracy of SVM is 90.97% with five frequency bands on 15 subjects (7 males and 8 females), while the average cross-subject classification accuracy is 64.82% using data from 14 subjects as training set and data from the rest one subject as testing set. This implies that different persons do share similar patterns for EEG changing with emotions, but there are still some individual differences during emotion processing. We also expand the training set from one subject to 14 subjects and find the average accuracy will then continuously increase with some slight ups and downs. Therefore, we can get an observation: A universally applicable EEG model for emotion recognition can be trained using data collected from enough subjects. Moreover, fuzzy-integral-based combination method is used to combine models across frequency bands and get an average improvement of 8%.

We choose data from the same or different genders to do cross-gender emotion classification, seeing Fig. 1. The better performance of using training and testing samples both from female subjects partly implies that there must be gender differences during emotion processing. Also, for female testing subjects, using single female model, or combining male and female models would both improve the performance of cross-subject emotion classification. Moreover, it can be partially illustrated that the universal EEG pattern is likely to behave more obvious among female subjects.
Emotion plays an important role in human communications and decision making. However, the modeling and mechanism of emotions still remain a challenge problem. Besides logical intelligence, emotional intelligence is proposed to narrow down the emotional gap between humans and computers in artificial intelligence. So far, many approaches to emotion recognition have been proposed based on different modalities. Among these approaches, emotion recognition from EEG allows direct assessment of emotional states of users, which has gained more and more attention recently.

In recent years, great progresses in EEG-based emotion recognition have been achieved and various methods have been studied and evaluated. However, a major limitation of these methods is that only a handful of features and classifiers have been compared in each study. Moreover, most studies evaluate their methods on different, usually small datasets, so the results of these studies cannot be compared directly due to different setups of experiments. It is difficult to judge which types of features and classifiers are most suitable for EEG-based emotion recognition. Although recently Jenke et al. performed a systematical comparison of feature extraction and feature selection methods in their work, there is still a lack of detailed comparisons of classification methods for emotion recognition form EEG.

In this paper, we review different classification methods for emotion recognition from EEG and perform a detailed comparison of these methods on a relatively larger dataset of 45 experiments. Since different classifiers could have different discriminative power for emotion classification, we further propose to combine different classifiers using stacking to improve the performance. Experimental results show that most relevant channels locate on the lateral temporal and prefrontal brain areas and the critical frequency bands are beta and gamma bands. Additionally, the weights of Logistic Regression-I2, SVM-linear and SVM-RBF indicate some relevant features in delta bands except for Random Forest.

To investigate critical brain areas and critical frequency bands for promoting our understanding of emotion processing mechanisms, we perform a contrastive analysis of the weights derived from the classifiers as a way to detect and extract the most relevant features for classification. We find that the relevant features of different classifiers are similar. These results show that most relevant channels locate on the lateral temporal and prefrontal brain areas and the critical frequency bands are beta and gamma bands. Additionally, the weights of Logistic Regression-I2, SVM-linear and SVM-RBF indicate some relevant features in delta bands except for Random Forest.

SP041.2 - Comparison of Classification Methods for EEG-based Emotion Recognition

1Computer Science And Engineering, Shanghai Jiao Tong University, Shanghai/CHINA, 2University of the Basque Country, San Sebastian/SPAIN

Emotion plays an important role in human communications and decision making. However, the modeling and mechanism of emotions still remain a challenge problem. Besides logical intelligence, emotional intelligence is proposed to narrow down the emotional gap between humans and computers in artificial intelligence. So far, many approaches to emotion recognition have been proposed based on different modalities. Among these approaches, emotion recognition from EEG allows direct assessment of emotional states of users, which has gained more and more attention recently.

In recent years, great progresses in EEG-based emotion recognition have been achieved and various methods have been studied and evaluated. However, a major limitation of these methods is that only a handful of features and classifiers have been compared in each study. Moreover, most studies evaluate their methods on different, usually small datasets, so the results of these studies cannot be compared directly due to different setups of experiments. It is difficult to judge which types of features and classifiers are most suitable for EEG-based emotion recognition. Although recently Jenke et al. performed a systematical comparison of feature extraction and feature selection methods in their work, there is still a lack of detailed comparisons of classification methods for emotion recognition form EEG.

In this paper, we review different classification methods for emotion recognition from EEG and perform a detailed comparison of these methods on a relatively larger dataset of 45 experiments. Since different classifiers could have different discriminative power for emotion classification, we further propose to combine different classifiers using stacking to improve the performance. Experimental results show that the combination of classifiers using stacking can achieve higher accuracies than single classifiers.

To investigate critical brain areas and critical frequency bands for promoting our understanding of emotion processing mechanisms, we perform a contrastive analysis of the weights derived from the classifiers as a way to detect and extract the most relevant features for classification. We find that the relevant features of different classifiers are similar. These results show that most relevant channels locate on the lateral temporal and prefrontal brain areas and the critical frequency bands are beta and gamma bands. Additionally, the weights of Logistic Regression-I2, SVM-linear and SVM-RBF indicate some relevant features in delta bands except for Random Forest.

SP041.3 - A Brain Computer Interface (BCI) based on intermittent photic-stimulation using multiple coherence to command detection

Author(s): Aluizio D’Affonseca Netto, Antonio M.F.L. Miranda De Sa, Antonio F.C. Infantosi

Biomedical Engineering, Federal University of Rio de Janeiro, RIO DE JANEIRO/BRAZIL

Brain Computer Interfaces (BCI) are systems that are capable of translating information from the neuronal activity of a subject into controlling signals for devices. BCI may be either passive or active. This latter uses evoked responses to external, sensory stimulation (e.g. intermittent photic stimulation). Active BCIs exhibit reduced complexity and processing time in comparison with passive interfaces. This occurs due to the fact that the evoked responses occur at a known stimulation, which simplifies the detection algorithm. The present work aims at using a modified algorithm for the multiple magnitude-squared coherence (MMSC) estimation for increasing both sensibility and specificity of the decision system, as well as to reduce the response time. The algorithms for multiple coherence calculation were developed using the sweep operator over the augmented spectral matrix. The algorithms for real time calculation and for obtaining BCI controlling signals with lowest latency. EEG from five subjects has been collected using the following monopolar derivations according to the 10-20 International System: O1, O2, P3, P4, C3, C4, Pz and Cz. The hardware was developed specifically for BCI interfaces based on visual stimulation. Each subject was seated in a comfortable armchair with a monitor containing four distinct LEDs each of which flickering at a distinct frequency (24, 28, 32 and 36 Hz). The multiple coherence detector was used to determine to which LED the subject was looking at and this result was used for a BCI that controlled the cursor movement. The MMSC-values were calculated with segments of L = 0.25 s of EEG signal segments. The proposed system is capable of detecting responses within a time lag that is below 4.54 s with average area under the ROC curve equal to 0.91. For a 24 Hz stimulation frequency, the system had sensitivity and specificity equal to, respectively, 88.3 % and 73.2 %. Fig.1 shows a volunteer controlling the cursor position using the BCI system.

Fig. 1. The weight distribution of LR-I2, SVM-linear, SVM-RBF and Random Forest.

Fig. 1 Average accuracies of cross-gender emotion classification.
The objective of this study was to evaluate a novel paradigm to control brain-machine interfaces (BMI) that has emerged from the need of creating BMI systems that feel natural and intuitive to the user. The first demonstration of such systems started over 40 years ago with a series of studies in which monkeys volitionally modulated single neuron activity through biofeedback. These systems exploit the volitional drive on cortical neurons that allows them to modify their tuning properties through a process of reward-modulated spike-timing-dependent plasticity. Recent studies have employed this alternative strategy to control motor neuroprosthesis and computer cursors, proving that single neuron activity is a promising signal for BMI control because of its greater simplicity to implement and to use.

The objective of this study was to evaluate a novel paradigm to elicit volitional modulation of neural activity in a rat model to control a two-degree-of-freedom BMI. In order to do this, we implanted microelectrodes in the motor cortex and trained the rat to modulate the activity from one selected neuron and maintain the firing target rate for up to 3 seconds. When the rat reached a low-rate target a food pellet was dispensed, while sucrose solution was dispensed with a high-rate target. The rat was free to choose whichever reward it wanted to obtain during the conditioning sessions. Biofeedback was provided in real-time through a LED that varied in brightness. We increased the difficulty of the task by incrementing/decrementing the firing rate thresholds or by increasing the hold time every 5-10 minutes.

In a previous study, we showed that the intrinsic spiking properties of cortical neurons determine the performance in a BMI task. We found that fast-spiking neurons are able to quickly adapt to arbitrary rules, while regular-spiking neurons cannot adapt in short periods of time.

In this study, the rat successfully learnt to control two degrees of freedom with fast-spiking neurons. In total, 7 neurons were used to control the BMI. Some interesting observations include: (1) the rat initially preferred to obtain food pellets (low-rate targets) in the first half of the session and abruptly switched to sucrose solution (high-rate targets) in the second half of the session; (2) the rat successfully suppressed the activity of the neuron and at the same time, was then able to generate bursts of high activity with the same neuron and maintain it for as long as 3 seconds; (3) in the last 3 days of training, the rat no longer showed such marked reward preference during the sessions, but instead learnt to balance the amount of food/sucrose solution rewards obtained in each experiment.

Further work is needed to probe the capabilities and limitations of using operant conditioning of neural activity to develop robust and reliable BMI systems, but we firmly believe this paradigm holds great promise to restore movement after paralysis.

**Objectives**

There is growing interest in the use of brain-computer interfaces (BCI) for rehabilitation of neurological conditions such as stroke. We have developed functional electrical stimulation (FES) therapies and technologies for almost two decades achieving remarkable restoration of upper limb function. In FES therapy, patients attempt specific functional tasks (e.g., lifting a mug from a table) and, simultaneously, the movement is facilitated with electrical pulses applied to the arm/hand. We are now combining our FES systems with a BCI to assist the efficacy of FES therapy when matching the intended and facilitated movements. The objective of this work was to explore the possibility of identifying specific hand grasps, performed with the same limb, using EEG analysis.

**Materials and Methods**

Fifteen participants (mean age was 32 and six were women) with no known neurological conditions performed six hand movements in a ready-go-stop sequence while we recorded EEG signals (C1, C2, C3, C4, Cz, F3, F4, and Fz). Four of the movements are commonly trained during stroke rehabilitation (two-finger pinch, palmar and lumbrical grasps, and hand opening — all finger extension). The movements were repeated at least 30 times with the participants’ self-identified dominant hand, and four of the subjects repeated the experiment with their non-dominant hand.

The time-resolved spectra (256-sample Hamming window, 128 sample overlap, 256-FFT) between 1 Hz and 50 Hz for all EEG recordings were smoothed and correlated with a hyperbolic tangent function to identify decreases in power (typically associated with the preparation and execution of voluntary movement). The spectral components and time ranges with the largest correlation values resulted in movement-specific maps that were used as features to implement a nearest-neighbour classifier.

**Results**

For all participants, at least three dominant hand movements were identified correctly with accuracies between 64%-75%, and 67%-85% when the non-dominant hand was used. We found a difference in accuracy for only one of the movements when the analysis was limited to only ipsilateral or contralateral electrodes. Classification of the different intended movements took place 1.2s (+/- 0.8s) to 0.7s (+/- 0.9s) before dominant hand movement onset and 0.7 s (+/- 0.9 s) to 0.4 s (+/- 0.4s) for non-dominant hand movements.
Conclusions

Our results are comparable to other reports describing the prediction and identification of movements performed with the same limb (92% [1] and 45% [2] with 163 and 128 EEG electrodes, respectively). However, the work presented here uses a maximum of eight EEG electrodes increasing its viability for use in a clinical environment. Our next steps will consist of testing the presented procedure with stroke and spinal cord injury patients. To the best of our knowledge, this is the first report on the analysis of EEG activity to predict specific hand movements targeted in stroke and spinal cord injury rehabilitation performed with the same limb.

SP041.6 - Wireless Distributed Intracortical Neural Interfacing: A New Approach for Brain Machine Interfaces
Author(s): AliReza Zabihian1, Amir Massoud Sodagar2, Mohamad Sawan1
1Electrical Engineering, Polytechnique Montreal, Montreal/CANADA, 2Electrical And Computer Engineering, K.N.Toosi University of Technology, Tehran/IRAN

Brain Machine Interfaces (BMIs), as promising devices for assisting patients with motor disabilities and/or neurological injuries, demand for high-performance recording/simulating capabilities in terms of speed, quality, and quantity, i.e. higher bandwidth, signal-to-noise ratio for neural signal, and interfacing area on cerebral cortex. In this abstract, we present the architecture of a wireless network of implantable microsystems.

There are three major approaches to electrically interface with the brain. They differ in spatial resolution, quality level of signal, and practical area to interface with. Electroencephalography (EEG) is a major approach to record brain activities using multiple surface electrodes on the scalp with poor spatial resolution. Electrocorticography (ECoG) utilizes surface electrodes mounting directly on exposed surface of cerebral cortex. Single-Unit Neural Interfacing is a method to measure single neurons electro-chemical activities (action potentials) using a microelectrode array system. In the last decade, Intracortical Neural Interfacing using wireless implantable microsystems with microelectrode arrays has realized wireless neural prostheses with higher spatial resolution, higher signal quality, and feasibility of freely movement of patient under study. But, in fact, the effective area covered with microelectrode arrays is too limited for most relevant applications.

Here, we propose a novel neural interfacing approach which is as high-performance as intracortical neural interfacing in terms of spatial resolution, quality of signal, and feasibility of freely movement; as well, similar to EEG and ECoG, it covers a significant area of cerebral cortex. The idea is to network several wireless implantable microsystems, which we call it Brain-ASNET: “Brain Area Sensor NETwork” (Fig. 1). To realize the proposed idea, there are many design aspects to be considered, including network architecture and protocol, and sensor node form factor and power consumption. We choose a star network topology, an ad-hoc TDMA MAC protocol, and OOK modulation in 902-928MHz ISM frequency band. The Custom Integrated Circuit (CIC) is designed and laid-out in an IBM 0.13µm CMOS process. The post-layout simulation results show energy efficiency of the designed ad-hoc network protocol and low power dissipation of the CIC. The whole chip, including all functional and peripheral integrated components, consumes 138µW and 412µW, at 1.2V, configured in a synchronized network as a sensor node and the coordinator, respectively.

At the congress, we will present design and implantation aspects of the proposed network, including proposed network architecture and protocol design, the CIC design, and a conclusion will be presented.

Fig. 1. Illustration of the proposed Brain-ASNET approach

SP041.7 - Design and construction of a brain-computer interface for applications in neuro–robotics
Author(s): Alma R. Méndez Gordillo, Marco A. Espinosa Medina, Miguel Villagómez Galindo
Mechanical Engineering, Universidad Michoacana de San Nicolás de Hidalgo, Morelia/MEXICO

A brain computer interface (BCI) is a device that helps people with motor impairments, to communicate externally using the electrical activity of the brain without the assistance of peripheral nerves or muscle activity, promising further improved quality of life of patients. This investigation presents the design and construction of a neural interface in order to study the signals produced by the brain, using a Mindwave mobile prototype device, which measure spectra power of EEG (Electroencephalography, i.e. alpha waves, beta waves, etc.), NeuroSky eSense meters (attention and meditation) and eye blinks in a safety way. As the main objective is to control 3 axis biomedical devices, particularly a robotic arm Model: K-680 Steren, it is important to highlight the contribution of this work in the control, which will be held through Matlab and ArduinoIO programs.
Medical device systems Health Technology Management (HTM) strategies and best practices are now well established in most first world and many developing countries\(^1\). Plans are underway to address identified gaps in HTM, e.g., appropriate equipment selection and lifecycle management. One approach is the 25 years of HTM Seminars provided by WHO-PAHO, IFMBE CED, and ACCE to 70 countries\(^2\).

There is a new emerging challenge in this space as well, that is the requirement for medical device integration into electronic health records to improve quality and safety of care\(^3\).

The Keynote will review this HTM progress, gaps, and new challenges. It will provide a framework to move us forward in collaborative fashion.

SP042.4 - Multi-criteria decision analysis to redesign an Italian Clinical Engineering Service under specific needs and regulation requirements

Author(s): Irene Lasorsa\(^1\), Giulia Abis\(^1\), Barbara Podda\(^2\), Agostino P. Accardo\(^2\)

\(^1\)Department Of Engineering And Architecture, University of Trieste, Trieste/ITALY, \(^2\)Clinical Engineering Service, ASL 5, Oristano/ITALY

The aim of this study is to fulfill the need of re-engineering the Clinical Engineering Service in an Italian ASL (Local Health Authority) located in Sardinia, in accordance with the Italian regulations for healthcare.

SP042.3 - Development of a scoring system to support medical equipment replacement prioritization using the Analytical Hierarchy Process (AHP)

Author(s): Paul Prowse, Kyle Eckhardt, Sarah Kelso

Clinical Engineering, Winnipeg Regional Health Authority, Winnipeg/ CANADA

The Winnipeg Regional Health Authority’s (WRHA) current approach to medical equipment prioritization is based largely on anecdotal evidence and qualitative information provided by the staff who use the equipment. A group of stakeholders representing clinical programs determines how the equipment is ranked for replacement through a peer-to-peer democratic process. However, the voters have little understanding of the true urgency of equipment replacement for the other clinical programs, so votes are won based on the ability of the program to present a compelling argument. The WRHA’s Clinical Engineering Program sought to develop a universal scoring system based on objective criteria to assist in this prioritization process.

A literature review revealed several scoring systems that have been developed utilizing a wide variety of criteria. From these criteria, four were selected for consideration: age, repair cost, reliability, and risk level. These were selected because they are frequently reported as predictors of replacement priority, and also because they could be universally applied to all equipment based on information available in our in-house Computerized Maintenance Management System (CMMS).

Previous studies have applied relative importance weightings to their chosen criteria based on expert opinion. Few have used a systematic approach, however, to determining the respective weightings. In the newly developed system, the pairwise comparison approach of the Analytical Hierarchy Process (AHP) is employed to determine weights that accurately represent each factor’s contribution to a device’s replacement urgency. The AHP was completed by several multidisciplinary groups including clinical engineers, nurses, managers, and administrators. The results from each group and the literature review were averaged to establish the final criteria weightings.

With the weightings established, a score from 0 to 100 was applied to each electro-medical asset with a purchase value greater than $10 000 and recorded in our CMMS. A report of this equipment was distributed to each clinical program to highlight the replacement priority of their equipment as defined by this system. Provided with objective information, decision makers can be better informed about equipment that needs replacement.

Limitations of this system relative to our regional CMMS will be explored alongside the advantages of this process over those developed previously. A summary of the effectiveness of our work in the first year and an outline of our second phase goals will be presented.

Even if methods for processes redesigning in healthcare organizations are available in the literature, there are no recent evidences of their application in Clinical Engineering Services.

Among the multi-criteria techniques, in this work PAPRIKA was used, since it is an easy-to-use and intuitive method for multi-criteria decision making, based on decision-makers’ preferences.

We identified the decision makers’ criteria (Table 1) to be fulfilled and four different preference levels for each criterion (Table 2), as inputs of the method. Moreover four different scenarios were identified and, for each scenario and criterion, the decision makers selected the most suitable level. In order to reduce the number of pairwise comparisons among the preference levels associated to the identified criteria, the online software 1000minds, implementing the PAPRIKA method, was used.

After 460 steps, the software allowed to rank the four possible scenarios. The results show that the Alternative A2 (Outsourced management of some of the activities), weighting 68.8%, represents the best solution for the ASL, followed by the Alternative A1 (current situation), weighting 68.8%, and the Alternatives A3 (Compliant to the Italian Ministerial Program SIGAE 4, CONSIP) and A4 (FULL

SP042.5 - Developing a system to support equipment repair versus replacement decision making

Author(s): Sarah Kelso, Petr Kresta
Clinical Engineering Program, Winnipeg Regional Health Authority, Winnipeg/Canada

Within the Winnipeg Regional Health Authority there is currently no system in place to guide the process of deciding whether a device suffering a major failure should be repaired or replaced. While the question may not arise frequently, it was determined that a consistent, methodical approach would significantly improve the confidence of decision makers and equipment owners, when Clinical Engineering recommends proceeding with a costly repair, or equipment replacement.

The development of a repair versus replace decision making process encompassed three major pieces of work: define a maintenance approach, establish a process for decision making including factors for consideration, and identify the repair cost threshold at which device replacement should be seriously considered.

Thorough analysis of the repair history data for four sample fleets of equipment indicated a general trend of modest increases in repair costs with age over the study period, but no statistically significant relationship between age and repair cost or repair frequency was identified. Therefore, maintenance/replacement approaches based on the assumption that the equivalent annual costs of maintenance will surpass the projected equivalent annual cost of replacement cannot be directly applied.

A two-phase process for repair versus replacement decision making was developed. The first phase relies on a single repair cost limit, set at 50% of the device acquisition cost, to flag the most costly repairs for further review.

The second phase incorporates factors used for equipment replacement planning, determined through an extensive literature review, to evaluate whether a specific case supports repair or replacement. Ten (10) criteria were selected for this evaluation:

- Past repair cost,
- Age,
- Past reliability,
- Present labour effort,
- Manufacturer support,
- Estimated useful life remaining,
- Projected reliability,
- Condition,
- Past usage, and
- Future usage.

The repair cost threshold value of 50% of acquisition cost has been selected as a starting point. This is near the mid-point of the range suggested in the literature. In our case the limit will be applied to parts and external labour costs only (i.e. not in-house labour costs), and is therefore additionally conservative.

A Clinical Engineering standard operating procedure, evaluation worksheet, and communication template were created to support the process. Next steps will include defining applicability to equipment groups/types and limitations therein, clinical stakeholder (equipment owner) education and consultation, implementation across Winnipeg region, and monitoring and improvement.

RISK contract), both weighting 28.2%.

The application of the PAPRIKA method for redesigning the Clinical Engineering Service in compliance with national and regional requirements for hospital accreditation can be considered successful.

SP042.6 - An assessment of Preventive and Performance Maintenance Of Theater Equipment In Public Hospitals Kenya: Case study Five Public Hospitals.

Author(s): Philip A. Anyango
Medical Engineering, Kakamega County General Hospital, Kisumu/KENYA

Medical devices play a key role in health care delivery. They are vital for diagnosis, therapy, monitoring, rehabilitation and care. Effective management of these devices is required to satisfy high quality patient care, clinical and financial governance, including minimising risks of adverse events. Unless medical devices are managed proactively, the same types of adverse incidents happen repeatedly. Good medical device management will greatly assist in reducing their potential for harm.

Cases where life has been lost because of faulty equipment and where patients has been turned away due to non functioning equipment has been captured in both print and electronic media on Kenya. One of the results of the studies done on medical equipment countries cites non functional equipment, as one of the main cause. Lack of maintenance and inadequate funding were found to be the main cause. In the past two decades most countries in Sub Saharan Africa in collaboration with development partners have tried to put in measures to address the challenges including training of technicians, building and equipping workshops. However the challenge still remains. Operation room (theatre) is one of the hospital departments that handle emergency cases and therefore equipment used inside must be in an optimum state all the time.

This paper is about an assessment on preventative and performance assurance maintenance of theatre equipment in five public county referral hospitals in Kenya namely Kisumu, Vihiga, Homa Bay and Kakamega. These hospitals were sampled because of geographical location and high volume of patients handled.

The assessment focused on four major equipment used in operation room namely, anaesthetic machine, vital signs monitor, suction machine and electrosurgical unit. The main objective was to assess why equipment fail. Areas assessed included; Mode of service and maintenance, compliance to manufacturer’s guidelines., Stick on a dated ‘SERVICED’ label noting the next date due,, records of the activities carried, by whom, date and signature, availability of service manual, Training and certification of service engineers and possible challenges.

The findings were analyzed and Preliminary results were as follow

On Compliance with manufacturer’s guidelines it was found out that; Most maintenance is done by in house staff, Very few equipment are under service contract, Manufactures service and timeline instructions are not followed to the letter. Training and certification of engineers- No evidence of certification of service engineers, Records were not well kept. Major challenges identified included; Insufficient funding’ Inadequate staff and adequate skills

Ifrom the results it is evident that the way the equipment is maintained directly affects its performance, lifespan and quality of care to patients and the need for capacity of staff handling the equipment need not be overemphasised.

The paper recommends a comprehensive assessment be carried out in the entire country and should cover entire hospital.

SP042.7 - Mathematical Model for Reliable Maintenance of Medical Equipment

Author(s): Abdelbaset Khalaf
Clinical Engineering, Tshwane University of Technology, Pretoria/SOUTH AFRICA

This paper proposes a mathematical maintenance model that analyses the effect of maintenance on the survival probability of medical equipment based on maintenance history and age of the equipment. The proposed model is simulated in Scilab using real data extracted from maintenance history of Anaesthesia Machine from Draeger. The analysis using survival approach reveals that conducting preventive maintenance (PM) on the selected medical equipment had a positive impact on survival of equipment. The model is then used to analyse the cost of maintenance scenarios and an appropriate scenario is proposed for Anaesthesia machine. A new failure-cost model is developed which may be used to calculate the number of failures of equipment and the annual maintenance cost. The proposed models may be used as a planning tool for selecting maintenance strategies for various medical equipment.
SP043 - Women in BioMedical Engineering

SP043.1 - One thousand years of women in science
Author(s): Monique Frize
Systems And Computer Engineering, Carleton University, Ottawa/ CANADA

Since the beginning of documented history, in every epoch, women have made significant contributions in science and technology. The challenge, since historians have mainly concentrated on men’s work, is to find these women and discover what they have done. A few examples will be presented in this paper, but interested persons can find many books and websites with biographies of women in science and medicine. A few books and websites include women in engineering and technology.

In the 4th century, Hypatia of Alexandria (c.355-415) is said to be the world’s leading mathematician and astronomer of her time. She was a popular lecturer on philosophical topics, attracting many students and large audiences. In the middle ages, women became involved in alchemy, herbal medicine, midwifery, and science in its fullest meaning. For example, Hildegard von Bingen (1098-1179) mentioned heliocentricity nearly 400 years before Copernicus and speculated about universal gravitation 500 years before Newton, composed music, and wrote on medicine and natural history. The renaissance counts many women astronomers that include Sophia Brahe (1556-1643), Maria Cunitz (1610-1664), Maria Winkelmann (1670-1720) and Margaret Cavendish (1623-1673) who published extensively on natural philosophy and early modern science, including over a dozen original works. With revised works, this brings her total number of publications to twenty one. Women were also patrons and correspondents of men like Queen Christina of Sweden and Elizabeth von der Plat. The 18th and 19th centuries count numerous women involved in serious science and mathematics such as Laura Bassi, Maria Gaetana Agnesi, Émile du Châtelet, Christina Roccati, Mary Somerville and many others. Only in Bologna and Padua were women granted doctoral degrees in the 18th and early 19th centuries, before women in general were admitted to University starting from the 1870s.

The presentation is meant to stimulate interest in the discovery of women who came before us and especially to demonstrate the importance of collecting papers and archives on women, their life, and their work. The active participation of women in science activities in all epochs, in spite of important obstacles they faced, is a model for girls and women today, since it is much easier now to follow this path than it has been in all past eras. We should be truly inspired by these stories and dream in our own way about the road we wish to follow.

SP043.2 - Creating the Memories and Celebrating the Legacy of Women in Science and Engineering
Author(s): Ruby Heap1, Monique Frize2
1History, University of Ottawa, Ottawa/ON/CANADA, 2Systems And Computer Engineering, Carleton University, Ottawa/CANADA

For centuries, women around the world have actively participated in science and engineering, both formally and informally. Unfortunately, their contributions as innovators and producers of knowledge in these fields remain, to a large extent, unknown or understated. The history of women scientists and engineers is still in its infancy in a large number of countries. One major reason is their invisibility in traditional and established archives, which collected male records and tended to privilege the life and work of men; but another key obstacle has been these women’s inclination to underestimate their own accomplishments, with the result that most did not seek to preserve their papers, and neither did their family, friends, and colleagues. At a time when the call for more women in science and engineering careers resonates strongly within governmental, economic and academic circles, and when there is a strong consensus regarding the benefits of gender equity and increased diversity in these fields, there is a pressing need to provide current and future women scientists with an accurate and inspiring understanding of their past, to learn about the lives and contributions of those who came before them.

This session will discuss an ongoing Canadian initiative which aims to research, recover, and celebrate the lives of women through the creation of an Archives of Women Scientists and Engineers in Canada. Sponsored by the INWES-ERI (International Network of Women Engineers and Scientists-Education and Research Institute), this initiative was launched at a workshop held in September 2014 at the University of Ottawa. Close to 50 participants—engineers, scientists, archivists, librarians, historians, policy makers—discussed the Archives project, along with partners such as the University of Ottawa, IBM Canada, The Canadian Commission for UNESCO, the US Society of Women Engineers (SWE) and a grant from the Social Sciences and Humanities Research Council (SSHRC). An action plan was adopted by the participants and a multidisciplinary Task Force was established to help proceed with its implementation. The main features of the action plan will be discussed in this session: the first steps include building an inventory of existing archives in major local, regional, and national repositories, and in major professional associations and organizations in science and engineering; with the assistance of SWE, we also intend to produce a Best Practices Guide to the discovery, recovery, and preservation of archives (manuscript, printed, audio-visual, digital) on women scientists and engineers.

In this interactive session, participants are invited to exchange with the speakers on approaches, programs and projects that might be developed to document the lives and careers of members of their organisations, document public conferences and exhibitions, books, brochures, oral testimonies, and the preservation of records of scientists and engineers.

SP043.3 - Women In Bio-Medical Engineering In Kenya
Author(s): Salome W. Mwaura
Bio-medical Engineering, MBAGATHI DISTRICT HOSPITAL, NAIROBI/KENYA

Women are often referred to as the weaker sex and in most communities in Kenya, they are regarded as children. It takes a lot of time for male Managers of health facilities to accept them in decision making.

As a primary school going girl, we took my brother to the local district hospital but the Doctors could not fully diagnose his condition due to some equipment in the laboratory and X-ray department
malfunctioning. In my mind, I was wondering what could have been wrong with the equipment and I decided that when I grow up, I must study the course for repair of equipment in hospitals.

After my “O” levels, I got three carrier opportunities in Medical Laboratory, Nursing and Medical Engineering. With my little knowledge about medical engineering, and remembering the incident in hospital earlier, I chose to pursue Medical engineering.

In 1993, I was admitted for a three year Diploma course in medical engineering at Mombasa polytechnic. I joined the civil service in 1997 and I have worked in various hospitals including Kisumu and Nyeri level V and Mbagathi level IV. In 2006, I enrolled for a 2 Year Higher National Diploma course in medical engineering at the Kenya Medical Training College, Nairobi.

In 2006, I was appointed HOD of Bio-medical engineering Department at Mbagathi District hospital heading a team of 8 bio-medics of whom 6 were male. It was an uphill task but today, I can proudly say that my work relation with everybody is very good. I am always involved in decision making as concerns medical engineering in the hospital by the hospital management.

I have attended several trainings. GAME, an American NGO organised one on theatre and ICU equipment in Kisumu, another one by JICA in Nairobi and another in South Africa by SAFHE/CEASA. I have also been to DITEC, USA for an advanced course in X-ray and Imaging.

I am a Member of AMEK which I have served in several capacities, and currently am the Treasurer. I have attended several conferences organised by the International Federation of Hospital Engineering (IFHE). I attend all annual conferences/events organised by AMEK and biennial East African conferences organised by the East African Country associations on rotational basis, the most recent one was in Kigali, Rwanda in December 2014.

**Challenges**

Biomedical engineering in Kenya is male dominated. Hence, fighting for recognition and appreciation by bosses is a major challenge in the field.

When it comes to factory training, most opportunities are given to men in the ratio of one out of ten.

Working with bosses who come from communities that do not recognise women plays a major role in demotivating women in their day to day operations.

**Conclusion**

There is need to support these ladies who are doing everything possible to give quality work in medical engineering and give them a chance as they have the capability.

They also need to be empowered academically in order to shine better in the field.

**SP043.4 - Physics is a waste of your intelligence**

**Author(s):** Shada Wadi-Ramahi

Biomedical Physics, King Faisal Specialist Hospital and Research Center, Riyadh/SAUDI ARABIA

Going to physics was not an easy road. It was unheard of that students who score high in the Jordanian SAT go to science. My parents were outraged. Graduating first in class in 3.5 years, still did not convince them. I was wasting my time and college was a waste of their money.

Fast forward to 2003, I graduate with a PhD in Medical physics from the US. Time to go home. I land a position in the country’s leading cancer center, joining a team of 7 physicists. It was not easy to be the only one with a higher degree in physics, most of the problems though did not come from fellow physicists, but from the chairman who could not handle having a “doctor” female staff. In official communications I was always referred to as “Ms.” instead of “Dr.”. The excuse was “you are like my daughter”. Later the attitude escalated. In one of my earlier meetings with linac vendors in 2004, I challenged the representative of a company on one of his claims. The chairman annoyed that I spoke up, yelled “Hey girl stop this!” It took a good year before attitudes changed to formal behavior …. At least on paper.

The policies of the institution prevented discrimination, and later I became the head of medical physics. However, harassment came in many forms; it was encouraging male physicists (my subordinates) to side step me and report to the chairman directly, it was over-riding the staff work schedule often after I distribute it (something that never happened to the chief technician … a male), it was ridiculing my expertise even after I obtained ABR certification. It was stopping warning letters addressed to staff members who yelled at their supervisor (me). Harassment took many forms and shapes. Did I think about leaving? Yes, I wanted to go “back” to the US.

I loved my profession and I was determined not to let a male-dominated culture sway me off track. I am in my country contributing greatly to the treatment of cancer patients, and if I am not part of the force of change then I am a quitter. I endured.

Eleven years later in 2014, when I announced I am leaving to a position in another highly competitive institution in the region, my chairman gave me a counter offer and tried hard to convince me to stay. The offer was generous, and the emotions were real. It was a moment of vindication, my dedication to work and perseverance paid off. Alas, it was time to move on.

Women in science world-wide are a minority, in the Middle East they are a rarity. Women in science in the Middle East who assumes higher positions in par to their male colleagues are a species of their own.

I am proud of my achievements … I am proud to call myself a medical physicist … I am proud to call myself an Arab, but above all I am proud to be a woman.

**SP043.5 - Medical physics – or how a change in career path becomes a passion**

**Author(s):** Loredana G. Marcu

School Of Chemistry And Physics, University of Adelaide, Adelaide/SA/ AUSTRALIA

I was trained as a physicist in a country under transition after half a century of communism. I enjoyed being a student at the University of Timisoara (Romania) where I studied physics for six years under the guidance of some highly respected professors. After graduation, I was lucky enough to get a teaching position in my hometown at the University of Oradea, where, for the first time, I stood on the other side of the desk. While it was a great teaching experience, I felt that I needed something more for a fulfilled scientific life.

That was the moment of a life-changing decision: moving to Australia. In Adelaide, South Australia, I have been able to continue my scientific education in a specialised branch of physics that I fell in love with. I had the good fortune to be offered a scholarship to attain my PhD in Medical Physics. I got to work with an extraordinary group of people at the Royal Adelaide Hospital where I continued my career for nearly a decade. The people, the facilities and the working conditions all put together offered an optimal learning environment and a
SP044 - Bio-Impedance and Imaging (Other)

TRACK 01: IMAGING

SP044.1 - Personal Time-Varying Magnetic Fields Evaluation During Activities in MRI Sites

Author(s): Giuseppe Acri, Barbara Testagrossa, Giuseppe Vermiglio

Dept. Of Sastas, University of Messina, Messina/ITALY

A person moving in and around the MRI site may experience strong time-varying magnetic fields. The physical consequence of the time variation of the magnetic flux density is the induction of currents in body parts. In this paper the time-varying gradient exposure associated with the magnetic flux densities is evaluated and measured. The acquired data, obtained from a personal magnetic dosimeter, represent the magnetic flux density function, B = B(t), related to the operator movement inside the MRI site. Such data have been processed to evaluate the corresponding dB/dt curves, that were estimated by calculating the time derivative. All the measurements were conducted on a 3.0 T MRI site, dedicated to research procedures, in two different conditions: at first during routine patient positioning, and secondly, simulating an emergency. In both the measurement conditions, two dosimeters, with different acquisition times, were simultaneously used. They were positioned the first time on the operator’s torso and the second one on his head. The analysis conducted, simulating both normal and emergency conditions, demonstrated that the dB/dt peak values strictly depended on human motion through strong static magnetic fields, and, sometimes, exceeded the recommended limit. This consequence highlighted the necessity of drawing up, as in case of ionizing radiation, behavioural rules to be followed by workers and patients. Therefore it will be necessary to assess risk conditions in a proper manner.

SP044.2 - ECG Imaging of Ventricular Extrasystoles

Author(s): Olaf Doessel1, Walther H.W. Schulze1, Danila Potyagaylo1, Rainer Schimpf2, Martin Borggrefe2

1Institute Of Biomedical Engineering, Karlsruhe Institute of Technology (KIT), Karlsruhe/GERMANY, 2First Department Of Medicine - Cardiology, University Medical Centre Mannheim, Mannheim/GERMANY

Objectives: Frequent ventricular extrasystoles can lead to ventricular tachycardia and ventricular fibrillation and are therefore life threatening. They can be treated with RF ablation, provided the focus of the extrasystole is precisely known. Invasive ablation procedures can be accelerated significantly if the focus of the extrasystole is known beforehand from non-invasive measurements. This project aims at the localization of ventricular extrasystoles from Body Surface Potential Maps (BSPM).

Methods: 9 patients with frequent extrasystoles were selected. BSPM datasets and MRI images were acquired. The MRI data contained an enddiastolic dataset of the heart and a thorax scan. Heart, lungs, liver, spleen, stomach, kidneys and aorta were segmented. Tetrahedral meshes of typically 3000 nodes in the heart and 350000 nodes in the thorax were created for FEM calculations. A thorough localization and registration procedure for the electrodes was implemented. During the invasive procedure stimuli were given at various positions and the BSPM were measured. Finally the foci of the extrasystoles were ablated. Various algorithms of reconstruction of electrophysiological sources in the heart from BSPMs have been implemented and tested, e.g. Tikhonov (with and without bounds), activation times, model based optimization and Maximum-a-Posteriori (MAP) estimates. Thorough validation was carried out.

great source of inspiration. Radiobiology became my new passion, a field that I am continuously learning and which never ceases to amaze me.

In life circumstances and priorities change, so after ten years of learning, working and teaching in Adelaide, it was time to give something back to the country where I was raised and educated. I am now back on home soil where I have helped the Physics Department of the Science Faculty within the University of Oradea set up a Medical Physics training programme at both undergraduate and postgraduate levels. It is a wonderful feeling to pass on your own experience and teach students that have the same thirst for knowledge that I had at the beginning of my academic career. Medical Physics is a developing field in Romania and we need enthusiastic and well-trained specialists to raise this branch of science to European standards. The love and passion for this field should start from studenthood, and as the first woman medical physicist has once said “We must have perseverance and above all confidence in ourselves. We must believe that we are gifted for something” (Marie Curie).
by comparing the reconstructed foci with the ones found during the invasive ablation procedure.

Figure 1: Three examples of reconstructed transmembrane voltages together with the true location of the extrasystole (pink bullet). **Method:** Tikhonov 2nd order. Blue bar indicates the time of reconstruction in the ECG (extracted from the BSPM).

**Results:** Figure 1 shows three examples. A median error of 20mm was achieved. This is somewhat disappointing but agrees with other publications with thorough validation of ECG imaging. The various reconstruction methods tested in this project deliver good results in one patient and worse results in another – no algorithm is the clear winner for all patients. The model based optimization performs slightly better as compared to the other methods.

Discussion: Despite the fact, that all the reconstruction algorithms mentioned above show very good results in computer simulations, the strict clinical validation uncovers some deficiencies. The results support the hypothesis, that the model assumptions that underlay all reconstruction algorithms are not yet perfect.

**SP044.3 - Experimental Study on Amplitude Frequency of Acoustic Signal Excited by Coupling Magneto-Acoustic Field**

**Author(s):** Ren Ma, Shunqi Zhang, Tao Yin, Zhipeng Liu

Institute Of Biomedical Engineering, Chinese Academy of Medical Sciences, Tianjin/CHINA

Object To study the relationship between exciting source characteristic and magneto-acoustic signal, also explore the frequency corresponding relationship between exciting signal and acoustic signal applied on the experimental sample. Methods A practical system has been established to detect magneto-acoustic signal. While single period sine pulse current with different amplitude and frequency were loaded in the sample of straight copper wire, acoustic signal was detected synchronously. Amplitude and frequency of exciting current and acoustic signal were analyzed by using time-frequency method, which was adopted by short time Fourier transform STFT and shifted smoothing rectangle window. Then, comparative study was conducted basing on the processed data. Result Giving the current same frequency as well as different amplitude, linear relationship is obtained between the output amplitude of acoustic signal and current amplitude. However, giving the current same amplitude as well as different frequency, the corresponding frequency spectrum of acoustic signal show different variation law, and thus, there is great difference among the system functions. Conclusion Detecting system is highly sensitive to frequency. In order to acquire more information in the magneto-acoustic signal, both of detecting circuit SNR and acoustic transducer bandwidth should be promoted.

**SP044.4 - In vivo electric conductivity values of cervical cancer patients reconstructed with a 3T MR system for improved SAR determination**

**Author(s):** Edmond Balidemaj1, Peter De Boer1, Henny P. Kok1, Gerben Schooneveldt1, R.F. Remis2, C.A.T. Van Den Berg3, A.J. Nederveen1, L.J. Stalpers1, Johannes Crezee1

1Radiotherapy, Academic Medical Center, Amsterdam/NETHERLANDS, 2Technical University Delft, Delft/NETHERLANDS, 3University Medical Center Utrecht, Utrecht/NETHERLANDS

**Introduction:** Reliable tissue electrical conductivity ($\sigma$) values are required to determine the RF energy absorption for Hyperthermia Treatment Planning (HTP) or for Magnetic Resonance Imaging (MRI) for safety purposes. Currently used $\sigma$-values are mostly based on ex vivo measurements, and tumor $\sigma$ is mostly unknown. Our aim is to acquire in vivo pelvic tissue conductivity for muscle, bladder and cervical tumor using 3T MRI.

**Methods:** Conductivity values were reconstructed using Electric Properties Tomography (EPT) which is based on the measurable B1+ field. Earlier we have validated this method for the pelvic region using phantom experiments and in vivo simulations. In this study, MR measurements of 12 cervical (squamous cell) carcinoma patients and one uterine adenocarcinoma patient were used to reconstruct $\sigma$-values in tumor, muscle and bladder. For a reliable $\sigma$-reconstruction the composition of a particular tissue should be relatively homogenous and sufficiently large (>3cm). Thus the $\sigma$ of 9 tumors and 7 bladder fillings could be reconstructed. Results were compared to literature data.

**Results:** The reconstructed $\sigma$-values of muscle tissue were up to 35% elevated compared to literature values (Figure 1a). Moreover, the reconstructed $\sigma$-values of the bladder were up to 10 times higher than values currently used in human models for HTP (Figure 1b). Finally, for 75% of the squamous cell carcinomas the $\sigma$-values were 5-12% higher than the $\sigma$ of muscle tissue found in this study. The reconstructed $\sigma$ of the adenocarcinoma was 22% higher compared to muscle tissue.

**Discussion & Conclusions:** This study demonstrated the feasibility to measure the $\sigma$ of healthy tissue and tumors in vivo. The measured conductivities were higher than reported in literature, which could probably be explained by the higher blood and water content during in vivo conditions. A decrease of $\sigma$ after death has been reported for bladder corresponds to bladder wall tissue, the volume percent of which is lower than that of urine. However, this study shows that urine $\sigma$ is much higher and shows a large inter-subject variation. Future studies will determine to which extent the reliability of HTP improves when using these patient-specific $\sigma$-values. These results are further interesting for applications such as MR safety and RF coil design for MR systems.
Liquid lenses, which are basically a soft capsule of oil or water, have recently been demonstrated capable of adaptive tunable focus. Its curvature changes can be activated by various means, mechanical, thermal, electrochemical or electrical. In mechanical or pneumatically activated liquid lenses, change of liquid pressure or membrane stress can induce the curvature changes and thus the variable focus. Such variable focus liquid lenses have a compact and lightweight design with integrated actuator, simpler than hard lenses\(^1\). However, it does not have as good shape stability as hard lenses. The liquid capsule may sag under gravity if its size is larger than 1 cm. In addition, the liquid lens may deform in response to vibration, causing image distortion. In contrary, human crystalline lenses, which are made of gel, generally can function robustly despite orientation change and last for a long life time (>40 years).

Inspired by the human crystalline lens, we make use of solid-state silicone gel (Dow Corning Dielectric Gel Kit 3-4170) to build a tunable focus lens, which is electrically activated by an annular dielectric elastomer actuator. The annular dielectric elastomer actuator acts like ciliary muscles that control the eye’s lens accommodation. Initially when the actuator is idle, the gel lens is flattened under the membrane pre-tension. Upon activation by the annular actuator that elongates, the gel lens bulges. Our experiment showed that this gel lens can vary focus on the objects between 2.5 cm and 30 cm when activated under voltages in range of 0-3 kV at very small dc current of <20 μA. As such, the gel lens consumes low electric power of <60 mW to work robustly more than 10,000 cycles. Furthermore, miniaturization of the dielectric elastomer actuators in terms of membrane thickness could help reduce the driving voltage requirement. This gel lens showed good potential to be commercially adopted due to its enhanced shape stability.

**SP044.6 - Ultra-low-field MRI for improving spatial accuracy of bioelectric source imaging**

**Author(s): Koos C.J. Zevenhoven**
Department Of Neuroscience And Biomedical Engineering, Aalto University, Aalto/Espoo/FINLAND

In magnetoencephalography (MEG), one measures the extremely weak magnetic fields generated by electrical brain activity using an array of highly sensitive, typically superconducting magnetic-field sensors around the head. As a functional brain imaging modality, MEG surpasses functional magnetic resonance imaging (fMRI) in terms of temporal resolution and has a spatial accuracy superior to electroencephalography (EEG). However, the spatial accuracy is limited by coregistration, the procedure of aligning a structural image of the head with the MEG coordinate system. Typically, this is done manually by digitizing anatomical landmarks on the head in the MEG session and separately localizing corresponding points in a structural head MRI.
Besides errors in identifying and digitizing the anatomical landmarks in both modalities, manual coregistration contains errors produced by a number of factors, such as the head-position measurement in MEG, distortions in high-field MRI, skin movements, and small differences between supine and seated positions regarding the geometry of the soft brain and cerebrospinal fluid.

The spatial coregistration accuracy is important not only for the alignment of electrical sources with the anatomy, but also for the reconstruction of the spatial origin of the signals, which depends on the geometry of the head and the changes in electrical conductivity across different tissues. As models for source localization become more detailed, their sensitivity to inaccuracies in geometry and conductivity values increases. The volume currents being particularly important in EEG, an accurate model of the conductivity structure is required especially for full benefit of the complementary information of simultaneous EEG and MEG. A hybrid MEG-MRI system provides natural approaches to addressing these issues.

At Aalto University, Finland, we have built a hybrid MEG-MRI system based on an array of sensors based on Superconducting Quantum Interference Devices (SQUIDs). The MRI is implemented at ultra-low field (ULF), around 50 µT, and measured inside a magnetically shielded room. The SQUID sensors tailored for ULF MRI can also be used for MEG. Together with the common sensor array, high-precision ULF-MRI electronics, and a stable coil structure, our novel algorithms can transform the largely manual coregistration problem to a fully automatic calibration, thereby eliminating human error and achieving sub-millimeter accuracy.

We describe the current state of our system and present obtained images. We further discuss the unique possibilities, shown recently, of ULF MRI in current-density imaging (CDI), potentially allowing also the imaging of electrical conductivity using the same hybrid device. We describe our methods, computations, and experimental setups for implementing the methods in our hybrid MEG-MRI device, along with preliminary results. If successful, conductivity imaging combined with sub-millimeter automatic coregistration will provide significant improvements to MEG and EEG source localization.

At Aalto University, Finland, we have built a hybrid MEG-MRI system of simultaneous EEG and MEG. A hybrid MEG-MRI system provides natural approaches to addressing these issues. We describe our methods, computations, and experimental setups for implementing the methods in our hybrid MEG-MRI device, along with preliminary results. If successful, conductivity imaging combined with sub-millimeter automatic coregistration will provide significant improvements to MEG and EEG source localization.

SP045 - Molecular Imaging PET/SPECT: Part 1

SP045.1 - Quantitative accuracy of SPECT imaging with a dedicated cardiac camera: Physical phantom experiments

Author(s): Amir Pourmoghaddas, R Glenn Wells

Physics, Carleton University, Ottawa/Canada

Introduction

Recently, there has been increased interest in dedicated cardiac SPECT scanners with multi-pinhole designs and improved detector technology due to their improved count sensitivity and resolution over traditional parallel-hole cameras. However, the pinhole-colli- mator design introduces position-dependent attenuation, sensitivity and resolution variations. Differences in attenuation patterns and energy-spectrum responses compared to conventional SPECT scanners can also inhibit accurate measurement of activity distributions. Simple correction methods for these effects are easily implemented however their level of accuracy is unclear. In this study, we assess the quantitative accuracy and reproducibility of absolute activity measurements made using easily implemented correction techniques applied to controlled physical phantom experiments.

Materials and Methods

Activity in the cardiac compartment of an Anthropomorphic Torso phantom (Data Spectrum Corporation) was measured through multiple 99mTc-SPECT acquisitions (n=10). The ratio of activity concentrations in organ compartments resembled a clinical 99mTc-sestamibi scan and was kept consistent across all experiments (6:1 heart to background, 1:1 heart to liver, 6:4 heart to lung ratio). To assess the effect of activity spill-in and increase scatter into the myocardium compartment, experiments were repeated with- and without activity in the soft-tissue torso compartment. The true net activity in each compartment was measured with a dose calibrator (CRC-25R, Capintec Inc). A ten minute SPECT image was acquired using a dedicated multi-pinhole cardiac camera with cadmium-zinc-telluride (CZT) detectors (Discovery NM530c, GE Healthcare), followed by a CT scan for attenuation correction (AC). Data were reconstructed with no corrections (NC), AC and AC with dual energy window (DEW) scatter correction (ACSC), using reconstruction with resolution recovery.

Results

T-tests comparing hot- and cold torso datasets (Table 1) showed no significant mean difference for all three reconstruction methods (NC, AC, ACSC: hot vs cold torso) (p>0.08). AC and ACSC significantly reduced the mean error over NC (p<0.001). The mean AC and ACSC errors were significantly different for the hot torso (p=0.04) but not for the cold torso (p=0.09), highlighting the effectiveness of DEW-SC in reducing errors introduced by photon scatter. While DEW-SC seemed to increase measurement uncertainty compared to AC in both cases, the increase was not significant (p=0.2). Both AC and ACSC significantly increased uncertainty over NC for the cold torso phantom (p<0.03), but not for the hot-torso case (p>0.1).

Conclusions

CT-AC and an easily implemented DEW scatter correction significantly improve quantitative measurement of 99mTc-SPECT myocardial activity with a dedicated cardiac camera producing an error of <= 2.2 +/- 6.5%.
SP045.2 - The Impact of time of flight algorithm and PSF modeling on standard uptake value in clinical PET/CT imaging

**Introduction:** Time Of Flight (TOF) and Point Spread Function (PSF) modeling are the most advanced reconstruction algorithms in PET/CT which dramatically improve the image quality. The aim of this study was to evaluate the impact of TOF and PSF modeling on Standard Uptake Value which is commonly used by physicians for staging of metastasis and monitoring response to therapy.

**Materials and Methods:** In this study, a whole-body 18F-FDG PET/CT scan performed on 9 patients (BMI=25.4±1.21, 5.02±0.07 MBq per kg) using GE Discovery 690 PET/CT. The scanner was capable to reconstruct images with TOF, and also PSF modeling which is commercially named SharpIR algorithm. All PET data were reconstructed with HD+SharpIR (use for clinical report in this center), TOF, and TOF+SharpIR algorithms. 40 Focal points (short axis diameter of 1.1±0.38 cm) were identified, and a semi-quantitative analysis was done by using SUVmean for normal lung tissue, SUVmax, and SUV50 for metastases. Furthermore, impact of lesion size, and location on SUV variation were assessed. We also evaluated noise in the images without and with attenuation correction using the volume of interest (VOI)-based analysis on 17 myocardial segments.

**Results:** Our semi-quantitative analysis verify using TOF, and/or SharpIR algorithms significantly enhance SUVmax (15.95±3.38% for TOF, 33.01±3.1% for TOF+SharpIR), and SUV50 (16.37±3.43% for TOF, 34.4±3.23% for TOF+SharpIR) in compare with the image reconstructed using HD+SharpIR. The statistical analysis showed that for smaller lesions, TOF, and TOF+SharpIR lead to more robust changes in SUVmax, and SUV50 (P-value<0.05). Figures 1 shows weak correlation between lesion location and SUV enhancement for both TOF, and TOF+SharpIR algorithms (R²=0.11, R²=0.03 respectively, P-value<0.5). Despite lesions, SUVlung wasn’t affected by reconstruction algorithms. Image noise for TOF+SharpIR algorithm was similar to HD+SharpIR, but noise for images reconstructed with TOF algorithm were superior (p-value<0.001).

**Conclusion:** This study showed that SUVs of metastases are highly affected by reconstruction applied method. Based on our results, it can be concluded that it’s vital to consider effects of TOF, and SharpIR algorithms on accuracy of SUV.

---

**SP045.3 - Can Pacemaker and ICD degrade CT-Based Attenuation Corrected cardiac SPECT images?**

**Introduction:** Quantitative processing of myocardial perfusion is a questionable issue in the SPECT imaging due to the some artifacts such as attenuation. Although it has been demonstrated that CT-based attenuation correction (CTAC) technique can significantly improve the diagnostic accuracy of SPECT imaging, the presence of cardiac Pacemaker and ICD leads in CT imaging will impact the reconstructed myocardial perfusion SPECT image during the CTAC procedure. In this study we investigated and quantified the degradation magnitude of the metallic artifacts due to pacemaker and ICD leads on the CT-based attenuation corrected SPECT images using phantom studies.

**Materials and Methods:** A cardiac phantom with capability of including pacemaker and ICD leads was scanned in SPECT/CT scanner. Attenuation correction of the SPECT data was performed using the artefactual (metal artifact) CT images (Figure 1). Quantitative evaluation was performed between the actual activity and the measured activity concentration in the myocardial perfusion SPECT images without and with attenuation correction using the volume of interest (VOI)-based analysis on 17 myocardial segments.

**Results:** Quantitative analysis shows an overestimation of about 9% and 15% and an underestimation of about 6% and 11% in CT-based attenuation corrected SPECT images with pacemaker and ICD leads, respectively.

**Conclusion:** Since photoelectric interactions are more significant at CT energies and are dependent on atomic number, the metallic composition of pacemaker and ICD leads, especially ICD lead, can induce considerable artifacts on CT images. Despite the influence of cardiac lead-induced artefacts on inaccurate quantification of some segments of the myocardial perfusion SPECT images when using the CT-based attenuation correction process, however it does not induce erroneous clinical interpretation of the SPECT images corrected for attenuation using artifactual CT images. It can be concluded that implementation of down sampling and smoothing on the artifactual CT images for generation of attenuation map reduce the impact of metallic artifact during the CTAC of SPECT data.
SP045.4 - Impact of Point spread function modeling on tumor quantification in clinical PET/CT imaging

Author(s): Sahar Ahangari1, Pardis Ghaifarian2, Mehrdad Bakhshayeshkaram3, Mohammad Reza Ay

1Department Of Medical Physics And Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN, 2Pet/CT And Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran/IRAN

Introduction: Quantitative assessment of PET images is increasingly used in cancer staging and therapy monitoring. In PET, partial-volume effects and point-spread function cause inaccurate estimation of lesion size and uptake. By regarding PSF-modeling during reconstruction procedure, the spatial resolution of PET images improves and as consequence the partial volume effect reduces. The aim of the present study was to evaluate the impact of PSF reconstruction (HD+SharpIR) compared with conventional OSEM reconstruction (HD) in non TOF PET imaging on quantitative accuracy of the lesions with respect to the lesion contrast.

Materials and Methods: In this study 17 patients (BMI:25.1±0.84) with 100 lesions were scanned using Discovery 690 PET/CT scanner. The patients were scanned 60 minutes after intravenous injection of 370 MBq of FDG (5.25±0.11MBq/kg). Emission data were acquired at 2 min/bed. All images were reconstructed using HD and HD+SharpIR algorithms with 3 iterations, 18 subsets, and 6.4 mm FWHM of post-smoothing filter. Image quality was evaluated by calculating COV (coefficient of variance) for a 3 cm spherical region in liver. The quantitative analysis was performed by measuring relative changes of standardized uptake values (SUV) and lesion size based on lesions location, and contrast with and without PSF-modeling. Contrast was defined as max activity concentration at lesion to mean activity concentration in background.

Results: Average of liver COV for HD and HD+SharpIR were 9.14±0.36 and 7.38%±0.33 respectively. PSF modeling increased SUVmax by 12% compared with HD algorithm. The regression analysis showed that relative differences for SUVmax significantly increased with increasing lesion contrast (figure1, R²=0.41,p<0.001) and lesion distance from the central axis (R²=0.24, p<0.001). For lesions with contrast less than 3, SharpIR algorithm reduced the size of lesion to 4.36%, and for high-contrast lesions (contrast higher than 3) the size decreased up to 17.81%.

Conclusion: Image quality was improved by using of SharpIR algorithm. SharpIR performance was better in lesions with smaller size, further distance from the central axis and higher contrast. So the effectiveness of the algorithm is more in high contrast lesions.

Objective: This study presents the clinical significance of focal increased 18FDG uptake in the thyroid as incidentally identified on PET/CT for ovarian cancer evaluation. Ovarian cancer is known to metastasize to the thyroid resulting in clinical hypothyroidism.

Clinical History and Results: A 54 year-old female with papillary adenocarcinoma of the ovary, underwent 18FDG-PET/CT post-surgery evaluation. 18FDG PET/CT was performed 1hr post IV 18FDG of 370MBq, (Fig. 1). A focal hyper metabolic lymph node lesion was visible in the left lower posterior deep cervical region with volume=12.4cm³, SUVmax=12.6. Thyroid was enlarged, focal nodular with irregular hyper metabolic 18FDG uptake in both lobes. The left and right lobes’ nodule volume=(2.05; 2.4)cm³, and SUVmax=(9.58; 9.88) respectfully. The rest of the body showed normal and physiological 18FDG metabolism. Thyroid Function Test was advised.

Results of TSH=7.9 IU/L, Tg=18.9 ng/ml, suggesting diagnosis of lymphocytic thyroiditis or differentiated thyroid cancer. The histopathology of US-guided FNAB samples showed: papillary carcinoma and Hashimoto thyroiditis; classical type. Tumor location: in both lobes with largest diameter: 3.5 cm. Lymph vessel invasion: present.

The patient underwent total thyroidectomy followed by 131I ablation dose of 3700 MBq. Post therapy 18WBS and neck by pinhole showed three focal areas (3x2; 2x2; 2x1.8 cm²) of residual tissue in both sides of neck, (Fig.2).

Conclusions: Incidentally found hyper metabolism of 18FDG PET/CT in thyroid was due to papillary carcinoma, most probably metastases from ovarian cancer. Elevated serum levels of TSH hypothyroid and Tg were significant with incidental finding of focal increased uptake.

We recommend that for patients with ovarian cancer; metastatic disease to thyroid should be considered, especially when PET/CT scan showed focal hyper metabolic lesion in the thyroid or elevated TSH. Further work is needed aiming at assigning a threshold level of SUVmax in thyroid to differentiate benign from malignancy.

SP045.6 - Zinc material filter for scatter correction in Tc-99m myocardial SPECT Imaging: Heart thorax phantom study

Author(s): Nazifah Abdullah1, Syed Inayatullah Shah1, Ahmad Zakaria2, Abdul Rahim Md Shahrin3

1Allied Health Science, INTERNATIONAL ISLAMIC UNIVERSITY MALAYSIA, KUANTAN, PAHANG/MALAYSIA, 2Health Science, UNIVERSITI SAINS MALAYSIA, KUBANG KERIAN, KELANTAN/MALAYSIA, 3Radiology, INTERNATIONAL ISLAMIC UNIVERSITY MALAYSIA, KUANTAN/MALAYSIA

Objective: SPECT is one of the techniques which provide the high diagnostic accuracy for the assessment of myocardial perfusion. However, the limitation in the diagnostic accuracy in the presence of Compton scattered photons in the image data. And the procedure is more
Thus, this work focuses on the investigations into the effect of Zinc (0.1mm and 0.198mm) material filter on image quality. The anthropomorphic torso phantom was used to perform the experiments. Data acquisition was obtained with the dual head gamma camera (Infinia GE Hawkeye II), equipped with low energy high resolution (LEHR) collimators. The gantry performed a 90° rotation, thus covering 180° (dual-head) with thirty six projections using step and shoot acquisition and with total 2400 kcount. Matrix size 128 x 128 was used with window widths of the energy 20% by using a Tc99m source at 140 keV. The data was reconstructed by a filtered back projection method of Butterworth filter of order 10 and cut off frequency 0.4 cycles/cm was applied. The value of Chang’s attenuation correction method was applied by selecting 0.164/cm linear attenuation coefficient. Image quality was analyzed by measuring contrast of lateral, anterior and septal defect using system software Xeleris 2.0. Images tomogram in Short Axis (SA), Vertical Long Axis (VLA) and Horizontal Long Axis (HLA) were also analyzed visually using MATLAB software with and without material filter. Results show that the contrast of the defect-to-healthy myocardium for lateral defect decreased with implantation of material filter compared to without filter, but for anterior defect the results were vice versa. For the septal defect there were slight decrease and increase for Zn 0.1mm and Zn 0.198mm compared to without filter, respectively. For the signal to noise ratio, with usage of Zn 0.1mm, the results show progression for lateral, anterior and septal defect compared to without the filter but is shown decrease for Zn 0.198mm. There was an insignificant decrease for left-ventricle-(LV) to-healthy myocardium contrast with implementation of material filter compared to without a filter. Qualitative analysis shown enhancement image quality for image obtained from Zn filter compared to without a material filter. So the application of the material filter in SPECT imaging has the potential to enhance the quality of the images, so it can increase the accuracy in the interpretation.

Conclusions:

- For lateral defect there were slight decrease and increase for Zn 0.1mm and Zn 0.198mm compared to without filter, respectively. For the signal to noise ratio, with usage of Zn 0.1mm, the results show progression for lateral, anterior and septal defect compared to without the filter but is shown decrease for Zn 0.198mm. There was an insignificant decrease for left-ventricle-(LV) to-healthy myocardium contrast with implementation of material filter compared to without a filter.
- Qualitative analysis shown enhancement image quality for image obtained from Zn filter compared to without a material filter.
- The application of the material filter in SPECT imaging has the potential to enhance the quality of the images, so it can increase the accuracy in the interpretation.

**SP046 - Assessment of Radiotherapy Response**

**TRACK 04: RADIATION ONCOLOGY**

**SP046.1 - Early prediction of lung cancer recurrence after stereotactic radiotherapy using texture analysis of automatic graph cuts segmentations**

**Author(s):** Sarah A. Mattonen, David Palma, Cornelis J.A. Haasbeek, Suresh Senan, Aaron D. Ward

1Department Of Medical Biophysics, The University of Western Ontario, London/CANADA, 2Division Of Radiation Oncology, London Regional Cancer Program, London/CANADA, 3Department Of Radiation Oncology, VU University Medical Center, Amsterdam/NETHERLANDS

**Purpose:** Stereotactic ablative radiotherapy (SABR) is becoming a standard treatment option for patients with early-stage lung cancer, and can achieve local control rates comparable to surgery. However, following SABR benign radiation induced lung injury (RILI) appears as radiographic changes on computed tomography (CT) imaging. These changes can be tumour-mimicking, making it difficult to distinguish recurrence from benign RILI. Current approaches do not reliably detect recurrence within a year post-SABR. Our previous work has shown the ability of CT texture features calculated within manually delineated regions of interest to predict recurrence post-SABR. The purpose of this study was to evaluate the accuracy CT texture features extracted within automatically derived regions of interest for prediction of eventual tumour recurrence.

**Methods:** We analyzed 22 patients with 24 lesions (11 recurrence, 13 RILI). Two regions of common post-SABR changes were manually delineated: consolidative and ground-glass opacities (GGOs) shown in red and green respectively in Figure 1. The consolidative regions were also automatically delineated using a OneCut graph cuts algorithm with the only operator input being the single line segment measuring tumour diameter, normally taken during the clinical workflow. Surrogate GGO regions were approximated by automatic expansion of the consolidative regions. Within the GGO regions, second-order texture features from grey-level co-occurrence matrices were calculated. Classification was performed using a linear Bayes normal classifier and evaluated using cross-validation (CV).

**Results:** Leave-one-out CV on images taken 2–5 months post-SABR showed robustness of the entropy texture measure, with classification error of 26% and area under the receiver operating characteristic curve (AUC) of 0.77 using the automatic segmentation: the results using a fully manual segmentation were 19% and 0.80 respectively. Using our fully automated approach, AUCs for this feature increased to 0.82 and 0.93 at 8–14 months and 14–20 months post SABR, respectively, suggesting even better performance nearer to the date of clinical diagnosis of recurrence.

**Conclusions:** Texture features calculated within GGO delineated from a fully automated algorithm using only an input diameter measurement have shown the potential to predict recurrence in individual patients within 6 months of SABR, eliminating the need for any manual delineations. Based on our ongoing validation on a larger sample, we aim to develop a computer-aided diagnosis system which can be integrated into a physician’s workstation to improve their assessment of response post-SABR. This could allow for earlier salvage for patients with recurrence, and result in fewer investigations of benign RILI.

Parametric response map (PRM) analysis is a voxel-based image analysis method for predicting treatment response which shows promise as a means for guiding locally adaptive radiotherapy (RT) (e.g. sub-volume boosts). However to date, PRM predictive utility has been primarily verified with respect to global outcomes such as overall survival (OS). Here we investigated whether voxel-wise treatment response information can be inferred from a PRM analysis that has been correlated with OS.

PRMs were generated from rigidly registered MRI-derived apparent diffusion coefficient (ADC) maps (1 and 3 months post-RT) for n = 14 patients treated for high-grade glioblastoma. PRMs indicated whether each tumour voxel had undergone a significant increase, decrease, or no significant change in ADC. The fraction of the tumour volume (fractional volume) classified by the PRM as significantly increasing in ADC (FVinc) was the only PRM measure found to be significantly correlated with OS (p = 0.63, p = 0.02, Spearman rank test). FVinc values were then used to classify responding patients (R; OS > 18 months) in a receiver-operating characteristic analysis which produced an area under the curve of 0.92 (Fig. 1).

To investigate voxel-wise treatment response, the fraction of voxels in each PRM class that remained within the tumor boundary at 6 months post-RT was computed for each patient (Fig. 2). Despite the positive correlation with OS, significantly increasing ADC voxels (red) were found to be more likely to remain within the 6-month tumour volume compared to significantly decreasing voxels (blue) within the patient group.

In summary, the PRM showed potential for predicting both global and voxel-wise treatment response, however, the relationship between the two could not be directly inferred suggesting that rigorous validation for each target demographic is needed if the PRM is to be used to guide locally adaptive RT.

Using Magnetic Resonance Imaging Radiomics to Personalize Brain Metastases Treatment

Author(s): Sarah A. Mattoneni1, Timothy Pok Chi Yeung1, George Rodrigues2, Andrew Warner3, Carol Johnson1, Frank Lagerwaard3, Miguel Palacios2, Omar Bohoudi3, Aaron D. Ward3

1London Regional Cancer Program, London/CANADA, 2Department Of Oncology, The University of Western Ontario, London/CANADA, 3Radiation Oncology, VU University Medical Center, Amsterdam/NETHERLANDS

Purpose: For patients with brain metastases, early and accurate treatment selection is critical to maximizing quality of life and potentially extension to life. Prediction of response to stereotactic radiosurgery (SRS) informs personalized treatment selection. The classification of brain metastases as “homogeneous”, “heterogeneous”, and “ring-enhancing” has been shown to be predictive of overall survival (OS) after SRS [1], but is subject to inter-observer variability. Our objective was to improve OS prediction by developing and testing a radiomics software platform for quantitative assessment of brain metastases appearance.

Methods: Thirty-one brain metastasis patients (44 lesions) underwent routine gadolinium-enhanced T1 weighted magnetic resonance (MR) imaging prior to SRS. Each lesion was manually contoured and classified as “homogeneous”, “heterogeneous”, or “ring-enhancing” [1]. Image intensities were normalized using the brain ventricles as a statistical reference. Image features including the first-order image statistics, size and shape-based features, and gray-level co-occurrence (GLCM) textures averaged over 13 three-dimensional offsets were measured. Image features between the three contrast-enhancement groups were measured using the Kruskal-Wallis test followed by the Mann-Whitney U test. Correlations between image features and OS were evaluated using the Spearman correlation.

Results: The median time to compute 335 image features was 0.6 minutes/patient (range: 0.3 – 4.6) using a non-parallel and unoptimized MATLAB implementation. The three contrast-enhancement patterns showed significantly different first-order statistics (P < 0.0025) (Figure 1). Size and shape-based features and GLCM-based textures were not significantly different amongst the contrast-enhancement groups. Using the largest lesion in each patient as the index lesion, first-order energy showed a significant correlation with OS (rho = -0.61, P < 0.001). Range, 90th percentile, 99th percentile, surface area, normalized radial length entropy, correlation, and cluster prominence showed marginal correlations with OS (P < 0.05).
Figure 1. A heat map showing image features (columns) for each lesion (rows). Red and green indicate higher and lower standardized scores, respectively. (*), (†), and (‡) represent significant differences between homogeneous vs. heterogeneous lesions, homogeneous vs. ring-enhancing lesions, and heterogeneous vs. ring-enhancing lesions, respectively. A Bonferroni-corrected $P < 0.0025$ was considered significant.

Conclusion: First-order image statistics calculated by our radiomics platform correlated with expert qualitative classification of contrast-enhancement patterns, and first-order energy correlated with OS. Future work includes optimizing the calculation of GLCM-based textures and determining a combination of image features that can accurately predict OS for individual patients.

Reference

The purpose of this study is to explore whether Raman spectroscopy is able to assess the response of lung tumors and healthy lung tissue in mice following radiation therapy. 4T1 mouse breast cancer cells were injected intramuscularly to metastasize to the lungs at day 14. These, 4T1 cancer cells were injected subcutaneously into the flanks of 18 Balb/C female mice. Five additional mice were used as “normal lung” controls. After 14 days, cohorts of mice bearing tumors received 6, 12 or 18 Gy to the left lung with 6MV photons. Five mice were treated as “unirradiated tumor” controls. After 24-48 hours, lungs were excised and the specimens were sectioned for Raman measurements and pathologic evaluation using a cryostat-microtome. A total of 775 Raman spectra were collected; 107 from unirradiated normal lung tissues, 126 from unirradiated tumors, and 318 from tumors irradiated with 6, 12 or 18 Gy. Raman spectra were also collected from normal lung tissues of mice with unirradiated tumors (29) as well as irradiated (6, 12 or 18 Gy) tumors (195). Principal component analysis (PCA) and discriminant function analysis (DFA) were performed to analyze and interpret the results. Normal lung tissues and tumors were identified 100% of the time relative to pathologic scoring. Raman spectral data showed prominent results between unirradiated tumor and tumors receiving 12 or 18 Gy. Thus, in a model consisting of unirradiated and irradiated tumors (12 or 18 Gy) classification accuracies were 97.6%, 79.6%, and 80.5%, respectively, relative to pathologic assessment (see Fig.). Overall, 85.4% distinguishability was observed for unirradiated and irradiated (6, 12 or 18 Gy) normal lung tissues. Preliminary results demonstrate the promise for Raman spectroscopy in the prediction of normal vs. lung tumors as well as in the assessment of response of tumor and normal lung tissues following radiation therapy.

**Results**

32 patients were recruited, 27 completing all scans. On average, the GTV-T and GTV-N were reduced, at week 7 to 55±19% and 63±18% of their volume at week 0. Larger reductions were observed for all studied PET image features: on average, the GTVPET-T and GTVPET-N were reduced, at week 7 to 17±8% and 7±3% of their volume at week 0, and the SUVpeak was reduced by 33±4% and 41±8% for tumoral and nodal disease, respectively. On average, the maximum rate of change occurred early in the treatment for all image metrics considered in this study.

**Conclusions**

In a homogenous LA-NSCLC population, we have shown, using serial 4DCT and 4DPET images acquired during chemo-radiotherapy, that tumor anatomy and physiology change at different rate, and that the maximal rate of change in image features occurs early into treatment. These results may help determine the optimal time for adaptation of therapy. Correlation of image features and their respective rates of change with clinical outcomes is ongoing.
SP046.6 - Evaluation and Visualization of Radiogenomic Modeling Frameworks for the Prediction of Normal Tissue Toxicities

Author(s): James Coates1, Asha K. Jeyaseelan1, Norma Ybarra1, Jessie Tao1, Marc David1, Sergio Faria2, Luis Souhami3, Marie Duclos4, Issam El Naqa1, Fabio Cury2

1Medical Physics Unit, Department Of Oncology, McGill University, Montreal/QC/CANADA, 2Division Of Radiation Oncology, McGill University, Montreal/QC/CANADA

We explore techniques for the evaluation and visualization of radiogenomic data-driven models in an effort to investigate the integration of genetic variations (single nucleotide polymorphisms [SNPs] and copy number variations [CNVs]) with dosimetric and clinical variables in modeling radiation-induced rectal bleeding (RB).

One hundred and twelve (N=112) patients who underwent curative hypofractionated radiotherapy (66 Gy in 22 fractions) between 2002-2010 were retrospectively genotyped for SNPs and CNVs in six genes: XRCC1, XRCC3, VEGFa, TGFβ1, ERCC2 and SOD2. A logistic regression modeling approach was used to assess the risk of severe RB (Grade≥3) using dosimetric, clinical and biological variables. Statistical resampling based on cross-validation was used to evaluate model predictive power and generalizability to unseen data. Principle component analysis (PCA) and vector biplots were used to visualize the quality of model fit.

Biological variable XRCC1 CNV showed good overall fit to RB outcome data (p<0.001). When added to the logistic regression modeling, XRCC1 CNV improved classification performance over standard dosimetric models by 33.5%. No clinical variables were found to adequately fit the data.

As a proof-of-concept, we demonstrated that the combination of genetic and dosimetric variables could provide significant improvement in NTCP prediction using data-driven approaches. Moreover, we have shown that visualization techniques could aid in interpreting multivariate model predictions.
**SP047.2 - Validation of a Commercial GPU-Based Monte Carlo Dose Calculation Algorithm for use with an Elekta MRI-Linear Accelerator**

**Author(s):** Moti R. Paudel¹, Anthony Kim², Syed Ahmad³, Arman Sarfehnia⁴, Stephanie Lim-Reinders⁵, Sami Hissoiny⁶, Michel Moreau⁵, Arjun Sahgal¹, Brian Keller⁶

¹Department Of Radiation Oncology, University of Toronto, Toronto/ON/CANADA, ²Department Of Medical Physics, Sunnybrook Health Sciences Centre, Toronto/ON/CANADA, ³Medical Physics Department, Portuguese Institute of Oncology, Porto/PORTUGAL, ⁴Department Of Radiation Oncology, University of Toronto, Toronto/ON/CANADA, ⁵Elekta, Maryland Heights/MO/UNITED STATES OF AMERICA, ⁶Institute Of Medical Science, University of Toronto, Toronto/ON/CANADA

**Purpose:** A treatment planning algorithm from the commercial vendor Elekta® has been developed to be used with a future MRI-linear accelerator (MRI-LINAC). This is a GPU-based Monte Carlo dose calculation algorithm (GPUMCD) that is capable of modelling the magnetic field ($B$-field) associated with the MRI-LINAC. The purpose of this work is two-fold: 1) to validate the algorithm without the presence of the $B$-field as this algorithm can also be used to model a standard linac, and 2) to validate this algorithm, with the $B$-field activated, against an independent Monte Carlo algorithm (Geant4), as will be the case with the MRI-LINAC.

**Methods:** The research version of the Monaco TPS version 5.09.05 was used. This version contains the GPUMCD algorithm in addition to the XVMC algorithm that is in current clinical use. For the initial validation of the TPS for a standard linac, a beam model was created for an Elekta Agility linac for 6 MV. A heterogeneous phantom, simulating either bone-in-tissue, lung, tumour-in-lung, or steel-in-tissue, was designed and built to compare radiochromic film...
measurements with the ability of the TPS system to model the dose. We compared film measurements with the Monaco GPUMCD and XVMC algorithms and with the Pinnacle collapsed cone algorithm (CCC). In terms of B-field validation, an independent MC algorithm, Geant4 version 4.10, is being used to compare against Monaco.

**Results:** For the standard validation (no B-field), film measurements were done in the heterogeneous phantom for field sizes ranging from 1x1 to 10x10 cm², where a tumour in a lung was simulated, and these were compared with Monaco (1x1x1 mm³ dose grid resolution and 0.5% statistical uncertainty) and with Pinnacle. Our preliminary results indicate that Monaco GPUMCD algorithm shows good agreement with measurements for the comparisons done thus far. The largest differences were seen for the 1x1cm² field size, where the measured dose, in the lung region, was higher by 3.5% (compared to GPUMCD), 10% (compared to XVMC) and 14% (compared to CCC). Doses were relative to the depth of dose maximum and uncertainties will be discussed. There was negligible difference between the Monaco GPUMCD and XVMC algorithms for the other field sizes. The results for the B-field modeling are currently being generated and will be presented.

**Conclusions:** The Monaco GPUMCD algorithm showed good agreement with measurements. The agreement for this algorithm appears better at the small field sizes compared to Monaco XVMC and Pinnacle CCC algorithms.

### SP047.4 - 4D Monte Carlo simulation for verification of delivered dose to deforming anatomy

**Author(s):** Sara Gholampourkashi¹, Miro Vujicic², Raanan Marants³, Jason Belec⁴, Joanna Cygler⁵, Emily Heath⁶

¹Physics, Carleton University, Ottawa/ON/CANADA, ²Medical Physics, Ottawa Hospital Cancer Center, Ottawa/ON/CANADA, ³Radiation Medicine Program, The Ottawa Hospital Cancer Centre, Ottawa/CANADA

**Objective:** To develop a dose calculation method using 4D Monte Carlo (MC) simulations that accurately reconstructs and verifies the dose delivered to a moving anatomy during radiotherapy treatments. The method is to be used for accurate dose calculations of dynamic radiation therapy treatment plans such as VMAT (Volumetric Modulated Arc Therapy) and IMRT (Intensity Modulated Radiation Therapy).

**Methods:** Quasar respiratory motion programmable phantom was used for measurements with an Elekta Agility linac. A square beam of size 4x4 cm² was chosen to cover the tumor (1.5 cm radius) inside the lung insert of the phantom and the source to axis distance (SAD) was 100 cm. The beam was delivered to the phantom in static (no motion) and moving (1.8 cm respiratory amplitude) states. Doses were measured using calibrated EBT3 film and RADPOS 4D dosimetry system.

Treatment planning was performed with XiO Treatment Planning System (TPS). Dose calculated by XiO was compared against results from measurements and MC calculations.

The EGSnrc user code BEAMnrc was used for simulating photon beams from the Elekta Agility linac. The DOXYZnrc and def-DOSXYZnrc user codes were used, respectively, for static and deforming anatomy dose calculations on the phantom file created from 4D CT-scans of the Quasar phantom, using the same beam configurations as in measurements. Dose calculation voxels were 0.25x0.25x0.6 cm³. Varian’s Velocity software was used to perform the deformable image registration of the tumor in different respiratory phases to the tumor in the static anatomy. Deformation vectors were then extracted and input to the defDOXYZnrc code to model the phantom motion during the dose calculation.

SP047.5 - Clinical implementation of an EPID-based in vivo dose verification system for SBRT-VMAT delivery; catching errors

Author(s): Peter Mccowan1, Eric Vanuytven2, Timothy Van Beek2, Ganiyu Asuni2, Boyd Mccurdy1
1Physics And Astronomy, University of Manitoba, Winnipeg/CANADA, 2Medical Physics, CancerCare Manitoba, Winnipeg/CANADA

Introduction: Most linear accelerators (linacs) used for radiotherapy are equipped with a mega-voltage electronic portal imaging device (EPID). Literature has determined the EPID to be a reliable dosimetric device. The portal dosimetry research group at CancerCare Manitoba has developed a set of physics-based tools which utilize measured EPID data acquired during treatment in order to reconstruct the 3D in vivo dose delivered to the patient. Our model can also predict the in vivo dose similar to a treatment planning system (TPS). Due to the hypofractionated regimen of stereotactic body radiation therapy (SBRT) treatments, a verification of the inter-fractional dose could provide additional safety for the patient because any error in delivery, when compared to conventional treatments, would have a greater radiobiological impact on the patient. In this study, the results of a one year clinical implementation test of our dose verification system will be presented for lung and spine SBRT-VMAT treatments.

Methods: Our in vivo model employs an inverse dose reconstruction method which combines a back-projected measured EPID focal fluence and a predicted linac-head extra-focal fluence. The primary in vivo patient dose is calculated by taking the total incident fluence on the patient, converting it to TERRA, and performing a collapsed cone convolution with Monte Carlo derived point-based dose deposition kernels. In vivo patient scatter dose is calculated through convolutions of the incident fluence with a library of Monte Carlo derived patient scatter kernels. Heterogeneities are accounted for through radiological scaling of the dose deposition and scatter kernels via electron densities from CT data.

Overall, 43 lung and 13 spine patients were treated over roughly a one year period using a Varian 2300ix model linac operated in 6MV SRS-mode. Continuous EPID images were acquired every 1.25-2.50 seconds. Fractions sizes were between 1 and 8 while doses were in the range of 6 to 24 Gy. All per-fraction data were compared to the Eclipse TPS dose calculation. Mean percentage dose differences and 3%/3mm gamma analyses were performed to compare the low dose voxel (LDV) regions (containing 20% of prescribed dose) and the high dose voxel (HDV) regions (containing 80% of prescribed dose).

Results: Three of the lung patients had significant errors in all fractions: mean HDV percentage differences and gamma pass rates were 10-20% and 50% respectively. A review of these three and seven other patient treatment histories (with less significant differences) revealed errors due to anatomical changes, patient setup, planning, as well as disruptions in EPID image acquisition. An average gamma pass rate of 90.6±8.3% and mean percentage dose difference of 4.8±1.9% were determined in the HDV region for the ‘other’ 40 lung patients. Due to the greater complexity and heterogeneity of the spine treatments slightly less agreeable results were determined.

Conclusion: A robust, EPID-based in vivo dose verification system has been employed clinically to test its feasibility in capturing inter-fractional SBRT-VMAT delivery errors. Significant errors were found which should encourage a full clinical implementation.

SP047.6 - pGPUMCD, a GPU-based Monte Carlo proton transport code

Author(s): Daniel Maneval1, Benoît Ozell2, Philippe Després1
1Département De Physique, De Génie Physique Et D’optique, Université Laval, Québec/QC/CANADA, 2Département Génie Informatique Et Génie Logiciel, École polytechnique de Montréal, Montréal/QC/CANADA

Purpose: The most accurate dose calculations in proton therapy result from Monte Carlo algorithms. However their clinical implementation remains problematic due to long computation times. To accelerate these simulations, a GPU-based Monte Carlo transport code was developed. pGPUMCD is an adaptation for protons of GPUMCD, a validated GPU-based Monte Carlo code for photons and electrons. Implementation strategies and validation results are presented in this work.

Methods: In pGPUMCD, protons are transported in a voxelized geometry by a class II condensed history approach with a continuous slowing down approximation. Energy straggling is considered as well as multiple scattering. Ionizations are modelled and secondary electrons are not transported. Moreover, elastic and non-elastic nuclear interactions in water are considered based on an empirical model. pGPUMCD was benchmarked against Geant4. Simulations consisted in a mono-energetic, mono-directional circular proton beam of radius 1 cm impinging normally homogeneous or heterogeneous phantoms. Relative statistical uncertainties were derived from a history by history scheme and were below 1% in 1 mm³ cubic voxels containing 50% of the maximal dose. A Geforce GTX Titan was used in pGPUMCD while Geant4 simulations were done on a
Xenon-based CPU cluster. The evaluation of GPU/CPU acceleration was carried out without computation of statistical uncertainties and with a single 3.3 GHz Intel Core i3-3220 CPU.

**Results**: Considering only electromagnetic processes, proton transport with pGPUMCD yielded results within 6% of Geant4 values, with the largest errors in the Bragg peak for a speed-up factor of at least 300 compared to a single-core CPU execution. The transportation of one million protons of 230 MeV took 50 seconds with pGPUMCD and eight hours with Geant4. A complete dose validation is under evaluation with Bragg peaks, dose profiles and gamma studies for several materials and different energies.

**Conclusion**: GPUMCD now allows proton transport with pGPUMCD. Preliminary results suggest good agreement with Geant4 and significant savings in terms of computation times. Nuclear reactions in water were implemented in pGPUMCD and the validation is under investigation as well as the improvement of efficiency and computation time.

**SP048 - Dosimetry of Protons and Heavy Ions**

**SP048.1 - An Attempt to Predict the Proton Relative Biological Effectiveness using Radical Recombination**

**Author(s)**: Kiyofumi Haneda
Hiroshima international university, Higashihiroshima/JAPAN

Most proton treatment facilities have adopted a relative biological effectiveness (RBE) of 1.1 for proton therapy. However, most of the in vitro and in vivo studies indicate that the RBE of the spread-out Bragg peak (SOBP) protons increases with depth. The increase in RBE of proton beams on the SOBP is a well-known phenomenon that is difficult to quantify accurately in vivo studies. The reason for this explains that the RBE increases as linear energy transfer (LET) increases within the SOBP. The fact that intra-track radical recombination can indicate to produce fully competent lesions in room. The purpose of this study was to analyze an impact on radical recombination for the RBE in the SOBP proton beams. First, a depth-dose curve for the 210 MeV proton beam measured using a gel dosimeter and an ionization chamber. Second, the spatial distribution of the physical dose was calculated by Monte Carlo code system PHITS; the role of nuclear interaction was taken into account and the geometry of the apparatus was faithfully reproduced. The simulation results were compared with measured the depth-dose distribution and very good agreement was found, and the spatial distribution of an LET-weighted dose with threshold LET value (4.9 keV/μm) was calculated by the same code. Then, the relative distribution of the radical-recombination was calculated from the physical dose and LET-weighted dose. The relative distribution of the radical-recombination was calculated at each depth as the quotient of relative dose obtained using physical and LET-weighted dose. The agreement between the relative distributions of radical-recombination and RBE was good at the SOBP.

**SP048.2 - A correction method for absorbed dose estimation using TEP-TLS/SR1 in therapeutic carbon beam**

**Author(s)**: WeiShan Chang1, Yusuke Koba2, Shigekazu Fukuda2, Genichiro Wakabayashi1, Hidetoshi Saitoh1, Kiyomitsu Shinsho1
1Radiological Sciences, Tokyo Metropolitan University, Tokyo/JAPAN, 2National Institute of Radiological Sciences, Chiba/JAPAN, 3Kinki University, Osaka/JAPAN

**Introduction**: TEP-TLS/SR1, a slab type tissue-equivalent thermoluminescence dosimeter, has the advantage of acquiring 3D dose distribution in a single irradiation. This property is favorable to be a QA tool for radiotherapy. One of the difficulties by means of TLDs in heavy ion dosimetry is the LET dependence of thermoluminescent (TL) efficiency. It has been reported that LET dependence of TEP-TLS/SR1 can be observed in not only the TL efficiency but also glow curve. The high temperature ratio (HTR) estimated using glow curve is a function of LET. Therefore it is possible to correct TL efficiency without information of LET for therapeutic carbon beam dosimetry. **Purpose**: The relation between HTR and TL efficiency is clarified and the feasibility of TEP-TLS/SR1 for carbon beam dosimetry is evaluated. **Methods**: An in house TL readout system was used to obtain the glow curve with high accuracy and low uncertainty. Each TLD chip was calibrated individually by absorbed dose to water in 60Co γ-rays. The TLD chips were irradiated by a 290 MeV carbon beam to clarify the relationships of HTR vs. LET (HTR-LET) and TL efficiency vs. LET (εLET). HTRLET and εLET at 60Co γ-ray were normalized to 1. The normalized TL efficiency (εLET, Y) as a function of HTR (HTRLET, Y) was obtained from two relation-
ships HTRLET and εLET. The feasibility of HTR correction for the TEP-TLSD/SR1 was evaluated using a carbon beam. Results: The HTR increased with LET, and TL efficiency showed exponential decrease with increasing LET. Dose difference at SOBP region reduced from 20-30% to 10-20% after HTR correction. Conclusion: A correction method for determination of absorbed dose in therapeutic carbon beam using TEP-TLSD/SR1 was developed.

The normalized TL efficiency as a function of HTR.

SP048.3 - Biologically-weighted dosimetric quantities based on a multiscale approach
Author(s): Heidi Nettelbeck1, Hans Rabus1, Hugo Palmans2, Marion Bug1, Massimo Pinto2, Carmen Villagrasa2, Marta Bueno2, Sylvain Meylan3, Pedro Teles3

Particle therapy with protons and ions has gained increasing interest and its use has grown worldwide. Due to the different biological dose response of these types of radiation compared to high-energy photon beams, the current approach of treatment prescription is based on the product of the absorbed dose to water and a biological weighting factor. This method, however, is insufficient for quantifying the biological outcome of radiation, hence the need to define new dosimetric quantities that allow a separation of physics and biological processes.

“Biologically-weighted quantities in radiotherapy” (BioQuaRT) [1], a joint research project funded within the European Metrology Research Programme, uses a multiscale approach to lay the foundation for such new dosimetric quantities. This approach involves simulation and experimental techniques to determine the physical properties of ionising particle tracks on different length scales from a few nanometres (diameter of DNA) to micrometres (size of cell nucleus), which are then correlated with biological effects of radiation.

The present work focuses on the simulation aspect of the project – the development of a comprehensive multiscale simulation tool [2] that incorporates radiation interaction cross sections with DNA and production rates of radical species. This simulation tool is used to relate track structure characteristics at the nano- and micrometre level to biological consequences of radiation interaction, such as DNA strand breaks. This work has led to the development of existing Monte Carlo simulation codes dedicated to radiobiology, in particular PTRA [3] and Geant4-DNA [4], which is used as a base for the simulation tool. The incorporation of interaction cross sections of DNA-substitute materials (rather than the conventional use of water) as well as fragmentation cross sections used to derive DNA strand break probabilities are among the improvements.

This multiscale approach has the potential to underpin the definition of new biologically-weighted dosimetric quantities relating track structure to relative biological effectiveness in proton and ion beam therapy.

SP048.4 - Studies of Helium and Carbon Ion Fragmentation processes in Water and in PMMA, using versatile Semiconductor Detectors
Author(s): Giulia Arico1, Jan Jakubek2, S Pospisil2, Naruhiro Matsu-fuji3, Oliver Jäkel4, Maria Martisikova2
1Heidelberg University Hospital, Heidelberg/GERMANY, 2Institute of Experimental Applied Physics (IEAP), Prague/CZECH REPUBLIC, 3National Institute of Radiological Sciences, Chiba/JAPAN, 4Heidelberg Ion-Beam Therapy Center (HIT), Heidelberg/GERMANY

Background/Purpose:
Heavy ion radiotherapy enables a more conformed dose distribution to the target than conventional radiotherapy. Moreover, helium and carbon ions have additional advantages when compared to protons, such as a narrower penumbra. However, ions heavier than protons may undergo nuclear fragmentation processes within the patient. The consequence is a spectrum of lighter fragments which affect the delivered biological dose distribution. Currently there is a lack of knowledge regarding ion nuclear fragmentation processes. Our research aims to provide some of the relevant data. The information gained in this study might be used to benchmark Monte Carlo codes and to improve the accuracy of the treatment planning systems.

Materials and Methods:
We use a single particle registration technique to compare the fragments arising from ion beams crossing water and polymethyl methacrylate (PMMA), for different target thicknesses. Solid PMMA is often used in dosimetric measurements to replace water phantoms. The used Timepix detectors [Llopart et al. NIM A 581, 2007], developed by the Medipix collaboration, have a sensitive area of 1.4 cm² (256x256 pixels, 55x55 um pitch) and 300 um or 500 um
Results:

With the presented experimental setup, we analyse: 1) the percentage of primary ions which undergo fragmentation processes; 2) the number and kind of fragments arising from single primary ions; 3) the relative number of created fragments, for each fragment species; 4) the lateral particle distributions. Comparing the results obtained in water and PMMA targets with same water equivalent thickness, good agreement is achieved in thin targets, while greater differences are obtained above 100 mm-w-\text{eq} thickness. Monte Carlo simulations are also performed, for comparison.

Conclusions:

Timepix detectors are small and highly flexible devices, which enable to study fragmentation processes very close to the target. The presented comparison of ion fragmentation processes occurring in water and PMMA phantoms shows some limits in the equivalence of these two materials. The differences become higher with increasing the target thickness and should be carefully taken into account when PMMA is used in place of water for dosimetric purposes.

Acknowledgments:

Measurements are performed at the HIMAC and HIT facilities. This research is funded by the Deutsche Krebshilfe (project 110296) and by the JSPS (project PE14770). This work is carried out as research project 14H339 at NIRS-HIMAC, and in frame of the Medipix collaboration.

**SP048.5 - Monte Carlo study of secondary neutron dose for multipurpose nozzle in proton therapy**

**Author(s):** Sungkoo Che\textsuperscript{1}, Jin Sung Kim\textsuperscript{1}, Dae-Hyun Kim\textsuperscript{1}, Eun Hyuk Shin\textsuperscript{1}, Youngyi Han\textsuperscript{1}, Sang Hoon Jung\textsuperscript{1}, Yoonsun Chung\textsuperscript{1}, Jungho Kim\textsuperscript{2}, Hyoenser Park\textsuperscript{2}

\textsuperscript{1}Department Of Radiation Oncology, Samsung Medical Center, Seoul/KOREA, \textsuperscript{2}Center For Ionizing Radiation, Korea Research Institute of Standards and Science, Daejeon/KOREA

Two full rotating gantry with different nozzles (Multipurpose nozzle and Scanning Dedicated nozzle) with conventional cyclotron system is installed and under commissioning for various proton treatment options at Samsung Medical Center in Korea. Currently, an issue in proton therapy is to evaluate the influence of the secondary neutrons produced by nuclear interactions with the modules of nozzle and proton beam. In our proton facility, the multipurpose nozzle was composed of many modules such as scatterer, ridge filter, multi-leaf collimator (MLC), compensator, and aperture. Therefore, the purpose of this study is to investigate neutron dose in multipurpose nozzle for proton beam with Monte Carlo simulation.

A Monte Carlo studies with the Geant4 toolkit were performed based on multipurpose nozzle’s geometry (MLC, compensator, aperture, ridge filter, scatterer and etc) given by Sumitomo Heavy Industry and secondary neutron dose was simulated with 230 MeV proton beams and 5 cm SOBP using a 10 x 10 cm\textsuperscript{2} brass aperture in a 40 x 30 x 30 cm\textsuperscript{3} water phantom. At first, we calculated the neutron energy spectrum at water phantom surface. Next, we calculated neutron dose at isocenter, 20, 40, 60, 80, 100 cm distance from isocenter and compared with other research groups.

We used the phase space option of Geant4 toolkit to reduce the simulation time for repeated calculations and calculated neutron energy spectrum binned in 30 keV intervals on water phantom surface for wobbling beam at multipurpose nozzle. The portion of neutrons in the total neutron energy spectrum with energies less than 1 MeV and greater than 165 MeV were 53.5% and 43.8%, respectively.

Next, we calculated neutron dose at isocenter, 20, 40, 60, 80, 100 cm from isocenter and 2 different depths (surface and mid-SOBP) for the proton beam with and without water phantom. At a distance of 20 cm from isocenter, the neutron dose rapidly decreased because of the relatively small magnitude of the dose after lateral profile of the proton beam. In the water phantom, low energy neutrons were captured by an absorbing material (water) and high energy neutrons lost energy by inelastic collisions.

Neutron dose to water phantom for multipurpose nozzle under proton treatment conditions was simulated. The results of this showed comparable results with measured or simulated neutron dose of other proton therapy center. In future studies, we plan to investigate experimental measurement of neutron dose and validation of simulation data for treatment beam with additional neutron dose reduction method.

**SP048.6 - Investigation of the uncertainties involved in the low energy proton interaction in different MC-codes for proton therapy application**

**Author(s):** Lalageh Mirzakahian\textsuperscript{1}, Valerio Giusti\textsuperscript{2}, Shirin A. Enger\textsuperscript{1}

\textsuperscript{1}Medical Physics Unit, McGill University, Montreal/CANADA, \textsuperscript{2}Dept. Of Civil And Industrial Engineering, University of Pisa, Pisa/ITALY

Background: High precision external radiation therapy can be delivered by protons with a strongly increasing energy deposition that creates a narrow peak of dose, called the Bragg peak at the end of the particle’s range and with sharp lateral dose fall-off, allowing to tailor the dose distribution to the target volume. The Monte Carlo (MC) method is an accurate and rigorous tool to simulate radiation transport and score energy deposition in heterogeneous media such as the human body. MC techniques have been implemented clinically for dose calculations in radiotherapy. The electromagnetic processes are well validated in different MC-codes, however there are discrepancies in nuclear models for low energy protons and therefore production of secondary particles such as neutrons. Neutrons contribute to out of field dose and in the long term may cause secondary cancers especially in children and young adults.

**Aim:** To Implement more accurate physics models and cross section for low energy proton interactions to be able to study secondary cancer induction related to primary protons in a clinical set up.

**Method:** Depth dose measurements were performed in the Svedberg Laboratory (TSL) proton therapy center at Uppsala University, Sweden, for a Gaussian shaped, mono-energetic beam with a energy of 178.25 ± 0.2 MeV using Scanditronix p-Si diode. The TSL beam setup was modelled and simulated with MC-codes Geant4.10.00 and MCNP6. Calculations were performed with the standard available models and cross section libraries of each code as well as importing new sets of cross sections for proton transport below 200 MeV from the TENDL-2012 library. The primary (proton) and secondary particle fluence (proton, neutron and gamma), proton depth dose and neutron equivalent dose were scored. The secondary particle fluence was filtered by several physics processes to find the process that causes the largest difference.
Results and discussion: The depth dose from protons is in agreement for both codes and measurements. However, there is a significant difference between both versions of Geant4 and MCNP6 in production of secondary particles despite of the use of same cross section library. The default version of Geant4 underestimates the production of secondary neutrons and overestimates the production of gammas compared with the modified version. The main difference between the default and modified version of Geant4 is due to proton inelastic process. The difference between the codes needs further investigation. The calculated neutron fluence must be verified with measurements.

Conclusion: The accuracy of models and cross sections implemented in different MC codes affects the accuracy of the dose calculation for proton beams and estimation of secondary dose calculation.

SP049 - Nanotechnology in Radiation Therapy and Imaging: Part 1

TRACK 06: NEW TECHNOLOGIES IN CANCER RESEARCH AND TREATMENT

SP049.1 - A plasma electrochemistry reactor enabling the rapid, efficient, automatic and on-site synthesis of radioactive gold nanoparticles for brachytherapy treatments

Author(s): Mathieu Bouchard, Stéphane Turgeon, Marc-André Fortin
Centre de recherche du CHU de Québec, Quebec City/CANADA

Gold nanoparticles (Au NPs) are increasingly considered for use as radioactive sources (198Au) for prostate brachytherapy procedures [1], [2]. The range of the 198Au β-particle (0.96 MeV, ~ 11 mm in soft tissue, ~ 1100 cell diameters) is sufficiently long to provide cross-fire effects of a radiation dose delivered to cells within the prostate gland, and short enough to minimize the dose to healthy peripheral tissues. The integration of 198Au NPs into brachytherapy procedures requires the development of more efficient, safer, and more compact Au NP synthesis methods. Indeed, because of their relatively short half-life (2.7 days), 198Au NPs should ideally be synthesized on site (directly in hospitals) and upon request. However, the current NP colloidal synthesis methods invariably rely on the expertise of skilled chemists. The preparation of NPs with current techniques comes with several manipulation steps (ligand exchange, solvent exchange, purification procedures), which represent critical radioprotection challenges. Therefore, novel bench-top technologies must be developed to facilitate the automated production of 198Au NPs. Here we report on the development of a plasma reactor used to synthesize Au NPs based on plasma-liquid electrochemistry (Fig. 1a) [3]. In this reactor, an argon plasma is generated at the surface of an aqueous solution containing gold salts (AuCl4-) and surfactant molecules. This method yields a continuous production of stable Au NP suspensions directly in water. Within only 45 minutes, a 50 mL solution containing 1 mM of AuCl4- can be reduced into NPs with a reduction yield of 99.3 ± 0.7 %. Thus-synthesized Au NPs are readily capped with dextran, a biocompatible molecule widely used in vascular injection media. The diameter of Au NPs can be tuned by varying the initial concentration of dextran in the solution. Finally, an integrated UV-visible spectrometer is used to monitor the Au NPs growth kinetics and their final size (Fig. 1b: plasmon peak: 531 ± 3 nm for 5 nm diameter NPs, 570 ± 4 nm for 120 nm diameter NPs), which is necessary for quality control. Overall, plasma electrochemistry could enable the efficient, on-site and upon request production of 198Au NPs for a next generation of brachytherapy procedures.

SP049.2 - Dose Enhancement in Radiotherapy by Novel Application of Gadolinium Based MRIContrast Agent Nanomagnetic Particles in Gel Dosimetry

Author(s): Mahsa Amirrashedi Bonabi1, Nader Riyahi Alam1, Ahmad Mostaar2, Soheila Haghgoo3, Ensieyeh Gorji2, Ramin Jaberi3
1Medical Physics, tehran university of medical sciences, tehran/IRAN, 2Medical Physics, shahid beheshti university of medical sciences, tehran/IRAN, 3Food And Drug Organization, Pharmaceutical Department, tehran/IRAN

The primary goal of radiotherapy is increasing dose in tumor cells and sparing normal tissues. One of the novel ways to achieve this goal is enhancing tumor dose by high atomic number (z) materials. Using high-z radiosensitizers in tumor cells could increase the effect of radiotherapy treatments through increasing photoelectric cross section and number of auger electrons. Advancements in nanotechnology made it possible to use nanoparticles in cancer imaging and treatments. Although many studies have been done on radiosensitization by different materials, most of them have focused on the dose response in the presence of gold nanoparticles. Of our knowledge there is not any experimental study on the radiosensitizing by gadolinium oxide (Gd2O3) nanomagnetic particles in brachytherapy and megavoltage beam radiotherapy. In this study we evaluate dose enhancement properties of gadolinium nanoparticle which is an MRI contrast agent in complex form. Because of increasing relaxation time and high atomic number (z=64), Gd2O3 can be used in image-guided radiotherapy. In recent studies there was a great interest on MRI guided radiotherapy, so it could be efficient to use an MRI contrast agent simultaneously as radiosensitizer in radiotherapy. Herein, dose enhancement in the presence of gadolinium oxide nanoparticles with 0.1mM concentration in a gel filled phantom was investigated. The results show maximum dose enhancement about 15%±0.01 up to 22%±0.02 in brachytherapy by Iridium-192, however this value is about 3.8%±0.002 in external beam radiotherapy with 6 MV photons. Our study approved radiosensitization property of this value is about 3.8%±0.002 in external beam radiotherapy with 15%±0.01 up to 22%±0.02 in brachytherapy by Iridium-192, however nanomagnetic particles with 0.1mM concentration in a gel filled phantom was irradiated by four X-ray beams with different spectra. For both types of beams, the incident number of particles was 108. Five nm width water slabs were positioned at a variety of depths behind the GNP in order to obtain the dose distribution of secondary electrons.

Results
In both proton and X-ray simulations it was confirmed that the dose enhancement effect occurred in both the depth and lateral directions. The effective area in the X-ray beam was shown to be much larger than that in the proton beam. However, the dose enhancement by protons was more intense near the GNP compared to that by X-rays. The results suggest that if GNPs are absorbed into cells or cell nuclei in high concentration, proton beams benefit by higher radiosensitizing effects than X-rays.

Conclusion
The dose enhancement effects of a GNP exposed to proton and X-ray beams was investigated in order to show the difference of dose distributions. A larger effective area was formed by X-rays while a higher enhancement in the vicinity of the GNP was observed in the proton irradiation. The results in this study suggest that the appropriate GNP concentration should be chosen depending on the type of radiation in order to obtain the maximum radiosensitizing effect.

SP049.3 - Monte Carlo simulation of the radiosensitizing effect by gold nanoparticles: comparison between proton and X-ray irradiation

Author(s): Jihun Kwon, Kenneth Sutherland, Takayuki Hashimoto, Hiroyuki Date
Hokkaido University, Sapporo/JAPAN

Purpose
Radiosensitizer gold nanoparticles (GNPs) have recently drawn attention. GNPs target tumor cells by functionalizing proteins. When GNPs are irradiated, electrons are ejected, causing a dose enhancement effect. Although this effect is usually discussed in the context of X-rays, we have investigated the effectiveness under proton beam irradiation and shown that the dose enhancement occurs in both depth and lateral directions around the GNPs. In this study we compare the characteristics of dose enhancement between protons and photons.

Methods
The dose distribution around a 20 nm diameter GNP was calculated with the Geant4 Monte Carlo simulation toolkit for a 0.7 MeV proton beam and 6 MV X-rays. For the proton simulation, a GNP was exposed unidirectionally at 0.5 μm depth in a water box (10 μm × 1 μm × 1 μm) so that the Bragg Peak was formed at the approximate location of the GNP. In the X-ray simulation, two steps were used: (i) 6 MV photons were shot into a water cube (30 cm on a side) and the energy spectra was tallied by 1 nm diameter water spheres at 4 depths, (ii) a GNP inside a water box (10 μm × 1 μm × 1 μm) was irradiated by four X-ray beams with different spectra. For both types of beams, the incident number of particles was 108. Five nm width water slabs were positioned at a variety of depths behind the GNP in order to obtain the dose distribution of secondary electrons. In both proton and X-ray simulations it was confirmed that the dose enhancement effect occurred in both the depth and lateral directions. The effective area in the X-ray beam was shown to be much larger than that in the proton beam. However, the dose enhancement by protons was more intense near the GNP compared to that by X-rays. The results suggest that if GNPs are absorbed into cells or cell nuclei in high concentration, proton beams benefit by higher radiosensitizing effects than X-rays.

Conclusion
The dose enhancement effects of a GNP exposed to proton and X-ray beams was investigated in order to show the difference of dose distributions. A larger effective area was formed by X-rays while a higher enhancement in the vicinity of the GNP was observed in the proton irradiation. The results in this study suggest that the appropriate GNP concentration should be chosen depending on the type of radiation in order to obtain the maximum radiosensitizing effect.

SP049.4 - Colloidal quantum dots: radiation resistant nano-scintillators for radiation-based applications

Author(s): Marie-Ève Delage1, Marie-Ève Lecavalier2, Dominic Larivièrè2, Claudine N. Allen3, Luc Beaulieu4
1Département De Physique, Génie Physique Et D’optique, Et Centre De Recherche Sur Le Cancer, Université Laval, Québec/CANADA, 2Département De Chimie, Université Laval, Québec/CANADA, 3Département De Physique, Génie Physique Et D’optique, Et Centre D’optique Photonique Et Laser, Université Laval, Québec/ CANADA, 4Radio-oncologie Et Axe Oncologie Du Centre De Recherche Du Chuv De Québec, CHU de Québec, Québéc/CANADA

Purpose: CdSe quantum dots (QDs) optical properties have been investigated for many years. Their tunable luminescence emission peak, sweeping the visible range, has fed interest in these nanocrystals. Emission wavelengths are directly determined by the size of the QDs, which is well controlled during the nanocrystals synthesis. The choice of the scintillation light color provides flexibility for different applications and allows a predictable match to the best sensitivity range of photodetectors. In this work, we compare a novel CdSe colloidal quantum dots (cQDs) system with multiple layers to an existing CdSe/ZnS commercial sample. This study presents a radio-resistant scintillating quantum-dots formulation for multiple applications in different medical physics fields like dosimetry, imaging as well as other possible applications in nanotheranostics.

Methods: CdSe/CdS/Cd0.5Zn0.5S/ZnS multi-shell cQDs were grown through the successive ionic layer adsorption and reaction (SILAR) synthesis. The nanocrystals, in powder form, were incorporated to a fiber optic-based detector: the cQDs were placed at one extremity of a non-scintillating plastic collecting fiber, with the other extremity free to be coupled to a photodetector. A similar detector
was prepared with commercial CdSe/ZnS (Ocean NanoTech) QDs. Luminescence signal of the QDs was collected with a CCD camera (Apogee U2000C) to measure the integrated signal. Two devices were used to irradiate the QDs: an Xstrahl 200 orthovoltage unit for kV energies (120, 180 and 220 kVp) and a Varian Clinax iX for 6 and 23 MV.

Results: For all beam energies, scintillation intensity decreases as a function of dose cumulated. Damage caused by radiation creates trap states that enhance the proportion of charge carriers experiencing non-radiative recombination, hence decreasing their contribution to the scintillation light. This trend was already reported in the literature but here cQDs demonstrated a better resistance to radiation. For a 220 kVp beam energy, the multi-shell cQDs signal drop of 1.6% per kGy (38% decreases with 23.5 kGy of accumulated dose) compared to a 5% signal loss per kGy measured for the commercial monolayer QDs sample. Literature predicts larger signal drop at MV photon energies, between 500-700%/kGy for monolayer QDs. The commercial CdSe/ZnS QDs shows a similar behavior with a significant drop of 30%/kGy for a 6 MV beam energy, an effect not observed for our cQDs.

Conclusion: Loss of scintillation light production from initial measurement of our cQDs was found to be small and negligible for standard irradiation found in radiation therapy and medical imaging. Therefore, our multi-shell cQDs showed much better resistance to radiation than other commonly used CdSe/ZnS QDs. One could take advantage of this durability in making cQDs part of applications requiring a scintillating material, keeping in mind their particular property of size-tunable emission wavelength.

SP049.5 - Use of gold nanoparticles and pH-LIP (pH Low Insertion Peptide) to increase radiation effectiveness in cancer cells. 

Author(s): Michael Antoshi, Diluka Wijesinghe, Samana Shrestha, Robert Lanou, Yun Hu Huang, Thomas Hasselbacher, David Fox, Nicola Neretti, Shouheng Sun, Natallia Katenka, Leon N. Cooper, Oleg A. Andreue, Yana K. Reshetnyak

Institute For Brain And Neural Systems, Brown University, Providence/RI/UNITED STATES OF AMERICA, Formerly Of Physics Department, University of Rhode Island, Kingston/RI/UNITED STATES OF AMERICA, Physics Department, University of Rhode Island, Kingston/RI/UNITED STATES OF AMERICA, Department Of Physics, Brown University, Providence/RI/UNITED STATES OF AMERICA, Department Of Molecular Biology, Cell Biology And Biochemistry, Brown University, Providence/RI/UNITED STATES OF AMERICA, Department Of Chemistry, Brown University, Providence/RI/UNITED STATES OF AMERICA, Department Of Computer Science And Statistics, University of Rhode Island, Kingston/RI/UNITED STATES OF AMERICA

Gold nanoparticles have been shown to increase the effectiveness of radiation on cancer. Increased radiation effectiveness would allow for smaller radiation doses to be used on patients, reducing side effects; alternatively, more cancer killing can be achieved using the radiation doses currently in use.

Gold nanoparticles increase radiation effectiveness because they have a higher absorption rate than human tissue at photon energies around 100 keV, and because they release Auger electrons upon irradiation. The effect of these Auger electrons is very localized, which means that proper placement of the gold nanoparticles is crucial in optimizing the effect. In our recent experimental work, we used the cancer-targeting molecule pH Low Insertion Peptide (pH-LIP) to target the gold nanoparticles to tumors. pH-LIP has been shown to target tumors using the property that tumors are more acidic than normal human tissue.

Our experimental results show that the use of pH-LIP with gold nanoparticles causes a statistically significant increase in gold uptake by cancer cells, and that the gold nanoparticles locate mostly to the cell membrane. In a clonogenic experiment, cells exposed to gold and pH-LIP survived less well than control cells as well as cells exposed to gold nanoparticles alone, by a statistically significant amount.

These results suggest that the use of pH-LIP significantly improves the impact of gold nanoparticles on improving the effectiveness of radiation. In vivo studies are in preparation. Previous work by members of our research collaboration has shown that pH-LIP is capable of significantly increasing the amount of gold that locates to a tumor in a mouse model. Thus, it appears likely that pH-LIP will also increase the impact of gold nanoparticles on radiation effectiveness in mice.

SP049.6 - The use of nanoparticles to improve hadrontherapy

Author(s): Marta Bolsa-Ferruz, Erika Porcel, Noriko Usami, Katsumi Kobayashi, Olivier Tillement, Hynd Remita, Ryochi Hirayama, Yoshiya Furusawa, Vladimir Ivosev, Daniela Salado, Lenka Stefancikova, Sandrine Lacombé

Biophysics, Biophotonics, Institut des Sciences Moléculaires d’Orsay (ISMO), Orsay/FRANCE, Photon Factory, Institute Of Materials Structure Science, High Energy Accelerator Research Organization, Tsukuba/JAPAN, Institut Lumiere-Matiere, Lyon/FRANCE, Laboratoire De Chimie Physique D’Orsay, Université Paris Sud 11, Orsay cedex/FRANCE, Research Center For Charged Particle Therapy, National Institute of Radiological Sciences, Chiba/JAPAN

Radiotherapy, one of the main treatments in cancer, can be improved by the use of heavy atoms, as radiation enhancers. Many investigations are conducted in this area. The challenge is to increase the radiation damage on tumor whilst preserving healthy tissue by improving targeting. Recent developments in nanotechnology brought new perspectives by using nanoparticles, which can be specifically functionalized. We have shown recently that platinum nanoparticles enhance even more than platinum complexes the DNA damage induced as well by fast carbon ions [1], as by gamma rays [2]. This effect is not due to the nature of the incoming radiation but explained by the auto-amplification of electron cascades into the nanoparticles. This result finds strong interest for developing medical protocols such as hadrontherapy and nanomedicine.

Similar results were found with gadolinium based nanoparticles (GBN) which give the possibility to associate RMN imaging to radiotherapy. Furthermore, a decrease of mammalian cell survival was also observed when GBN are associated to ions radiation [3].

This last result allows us to measure how the use of heavy nanoparticles could improve treatments by enhancing efficiency and targeting of radiations into the tumor. The treatment could be simultaneously followed by MRI.

SP050 - Time-Frequency Analysis

SP050.1 - Frontiers of Neuroengineering
Neuroengineering field is seeing an explosive growth thanks to the major brain initiatives worldwide, and the belief that technologies that can push the scientific and clinical frontiers in brain sciences as well as diagnosis and treatment of the nervous system diseases and disorders. Technology is playing a key role from discoveries at cellular to whole brain level. Examples include nano and microprobes are used for recording from neurons, nerves and from many brain regions, and various imaging modalities using high resolution optical neuronal imaging to whole brain functional imaging. Neurotechnology is also playing a key role in diagnostic and therapeutic domains. Among the exciting frontiers are neural interfaces to restore function (limbs and visceral organs), treating brain disorders, neuropsychetics, and brain machine interfaces. This talk will overview the emerging technologies and key applications and successes driving the field of Neuroengineering as well as lay out several problems and challenges.

SP050.2 - Neural responses to hearing own names comparing with repeated/non-repeated unfamiliar stimuli

Author(s): Kaori Tamura, Toshiki Matsuo, Keiji Iramina
Graduate School Of Systems Life Sciences, Kyushu University, Fukuoka City/JAPAN

Neural responses to self-related stimuli have been investigated to reveal the function of self-recognition. Subject’s own name (SON) is the word which closely related to self-recognition process. The present study focused on this own name stimulus and examined neuronal responses to hearing SON by measuring and analyzing electroencephalography (EEG), comparing with hearing unknown names.

Our experimental sequence consisted of calling SON and unfamiliar names (UN) those have no relationship with each participant. By this experimental sequence, we performed EEG measurements and analyzed the collected EEG data by wavelet transform. Then we obtained event-related (de-)synchronization (ERD/ERS) in each condition from wavelet coefficients.

In SON, we found significant beta ERD, while sUN showed beta ERS at the same latency. The mean value of beta power in rUN was midway between those of SON and sUN. This linearity of beta power changes seemed to be related with familiarity levels. SON was the most familiar stimulus among the stimuli, and stimuli of sUN were completely not because they were presented only once. The familiarity of rUN could be increased by repetition during an experiment, though it was not familiar one before the measurement. Considering these results, we suggest that beta power changes related with the familiarity levels.

The spectral analysis using Fourier Transform (FT) formalism shown to be very useful in a wide range of MRS applications. However, this technique can be tricky in some cases where peak superposition occurs, a common situation during in vivo data quantification process. This work describes an unsupervised deconvolution algorithm using Krylov Basis Diagonalization Method (KBDM) with multiple signal truncation and clustering. The KBDM is a fitting algorithm based on Lorentzian model functions and its mathematical approach is described at [1-4].

We exploited the fact that varying the number of points of the signal (M) used to construct the matrices aforementioned leads to different representations of noise components to minimize its effect in the estimation of each signal component. We applied the method multiple times with different values of M, clustering its results with a density-based algorithm and averaging the values of each cluster.

Our results show that using the proposed processing strategy, KBDM-estimated values are highly consistent with simulated values for different sets of spectra and noise level. The effects of the noise in the spectral quantification was not found to be critical, at least for simulated data with signal-to-noise ratio equivalent to that typically found in clinical MRS at 1.5T. In summary, KBDM is a promising tool that can provide complimentary information to the well-established Fourier techniques, especially when overlapping peaks are present. Further studies are in progress in order to validate the proposed method for in vivo data processing.

SP050.3 - MRS data deconvolution through KBDM with multiple signal truncation and clustering: circumventing noise effects

Author(s): Danilo M.D. Da Silva1, Yule Vaz, Fernando F. Paiva
1Departamento De Fisica E Ciencia Interdisciplinar, Instituto de Fisica de Sao Carlos, Universidade de Sao Paulo, Sao Carlos/ BRAZIL
2Departamento De Ciencias De Computacao, Instituto de Ciencias Matematicas e de Computacao, Universidade de Sao Paulo, Sao Carlos/BRAZIL

The spectral analysis using Fourier Transform (FT) formalism shown to be very useful in a wide range of MRS applications. However, this technique can be tricky in some cases where peak superposition occurs, a common situation during in vivo data quantification process. This work describes an unsupervised deconvolution algorithm using Krylov Basis Diagonalization Method (KBDM) with multiple signal truncation and clustering. The KBDM is a fitting algorithm based on Lorentzian model functions and its mathematical approach is described at [1-4].

Basically, the output of the KBDM is a tuple (T2, frequency, amplitude and phase of each signal component) of M points obtained from a generalized eigenvalue equation of MxM matrices built using M points of the MRS signal. If only K Lorentzian components are present in the signal, the remaining M-K components will vanish for noiseless signal. When noise is present, it will be represented using Lorentzian components, which will lead to spurious components.

We exploited the fact that varying the number of points of the signal (M) used to construct the matrices aforementioned leads to different representations of noise components to minimize its effect in the estimation of each signal component. We applied the method multiple times with different values of M, clustering its results with a density-based algorithm and averaging the values of each cluster. The figure below shows the original noisy signal (top), the estimated signal using our method (middle) and the residual (bottom).

Our results show that using the proposed processing strategy, KBDM-estimated values are highly consistent with simulated values for different sets of spectra and noise level. The effects of the noise in the spectral quantification was not found to be critical, at least for simulated data with signal-to-noise ratio equivalent to that typically found in clinical MRS at 1.5T. In summary, KBDM is a promising tool that can provide complimentary information to the well-established Fourier techniques, especially when overlapping peaks are present. Further studies are in progress in order to validate the proposed method for in vivo data processing.

In vivo data processing.
Introduction: Rostral fluid shift during sleep can increase neck circumference (NC) and narrow the upper airway cross-sectional area (UA-XSA). Such narrowing in UA-XSA may increase turbulence of airflow passing through the upper airway; thus, induce snoring. The objective of this study was to investigate whether acoustic features of snoring change with the increases in NIV, NC and decreases in UA-XSA (100-4000Hz: r = 0.72, P = 0.019; 150-450 Hz: r = 0.73, P = 0.016) and UA-XSA (100-4000Hz: r = -0.71, P = 0.022; 150-450 Hz: r = -0.79, P = 0.006) were achieved in non-REM stage 2 of sleep.

Conclusion: Our findings suggest that an increase in NC and narrowing in the UA-XSA could increase snoring sounds’ power in various frequency ranges.

Method: Twelve men (age: 46±13 years, BMI: 26±3, AHI: 39±25) attended the sleep laboratory for a daytime sleep study. Subjects slept in supine position only, and their sleep was assessed by a regular polysomnography. NC and UA-XSA were measured before and after sleep using a measuring tape and acoustic pharyngometry, respectively. During sleep, snoring sounds were recorded with a microphone attached to the neck. Snoring segments were annotated manually by an expert. Snoring features such as duration and occurrence of snoring, average power for seven frequency sub-bands were extracted in various sleep stages as well as the entire sleep duration. Correlations between snoring features and changes in NC and UA-XSA were assessed by Pearson or Spearman’s correlations.

Results: Increases in NC after sleep were found to be associated with an increase in average power of the snoring sounds in the frequency range of 100–4000 Hz (r = 0.76, P=0.011) and of 150–450 Hz (r = 0.73, P=0.017). Furthermore, reductions in UA-XSA increased snoring sounds’ average power in the frequency range of 100–4000Hz (r = -0.70, P=0.025) and 150–450Hz (r = -0.64, P=0.044). Similar strong correlations between snoring sounds’ average power and changes in NC (100-4000Hz: r = 0.72, P = 0.019; 150-450 Hz: r = 0.73, P = 0.016) and UA-XSA (100–4000Hz: r = -0.71, P = 0.022; 150–450 Hz: r = -0.79, P = 0.006) were achieved in non-REM stage 2 of sleep.

Conclusion: Our findings suggest that an increase in NC and narrowing in the UA-XSA could increase snoring sounds’ power in various frequency ranges.
SP051 - Rehabilitation Robotics

SP051.1 - Biomechanical Simulation of Upper Extremities Exoskeleton to Aid Stroke Patients
Author(s): Yahia M. Al-Smadi
Mechanical Engineering, Texas A&M University - Kingsville, Kingsville/UNITED STATES OF AMERICA

Recently many efforts are carried out that can help people with restricted arm movement or rehabilitate injuries and disabilities. In this case exoskeleton is the most extensively used equipment to get rid of this restriction. Exoskeleton helps to boost strength and endurance as well as reduce the efforts required to perform various activities in day-to-day life.

In order to manipulate characteristic of the exoskeleton, we carried out two virtual experiments. Initially using Denavit–Hartenberg parameters, we patronized our model with number of degree of freedom. ADAMS and AnyBody simulations were carried out. We computed results of effects over human body with and without exoskeleton.

While studying exoskeleton effect on human arm, we studied several joints, muscles and bones reactions in different load conditions. We studied two different load conditions while concentrating on performance of the exoskeleton. The very first condition was constant load where as the second one is the variable load acting on the arm. In both the case we considered gravity force to get more precise result. Below shown graphs are some of the results which we have explained later.

SP051.2 - Testing a mobile robot toy for children with disabilities
Author(s): Adriana M. Rios Rincon, Daniel A. Quiroga Torres, Javier Castellanos, Maria F. Gomez Medina, Antonio Miguel Cruz, William P. Rodriguez
School Of Medicine And Health Sciences, Universidad del Rosario, Bogotá/COLOMBIA

Robots showed a potential to enhance engagement in free play of children with severe motor impairment, however, they are too expensive to be used in low-income settings. The objective of this study is to perform technical assessment of a prototype of a low cost car-like robot that can be operated by head movements for children with motor impairment. We designed a robot that and tested its technical features. We found that the robot power efficiency is low (47%), current peak for both motors were 474.4 mA (right) and 416 mA (left) both of them were below 2 Amp which is the maximum current limit threshold tolerated by the L293B component, as the robots get far away from the control the response time slightly increased.

The reaching distance of the remote control was 20.7 meters which is enough for using in therapeutic activities. Regarding the functional features, the robot moved forward in a straight line 86.6% of the tested trials (26/30) and was able to turn 90 degrees left or right 93.3% of the trials (28/30). The robotic prototype met basic technical and functional requirements. Power efficiency, safety and apparel features should be improved for being used by children with using for children with motor impairments.

SP051.3 - Pilot study of a soft metal hydride actuator for a wearable rehabilitation system
Author(s): Minako Hosono1, Kouji Sakaki2, Shuichi Ino2
1Industrial Research Institute of Shizuoka Prefecture, Shizuoka/JAPAN, 2National Institute of Advanced Industrial Science and Technology, Tsukuba/JAPAN

A prototype actuator for a wearable rehabilitation system was proposed in this study.

A wearable rehabilitation system has a potential to play an important role in remote rehabilitation to free patients from stressful constraints. It is essential for such a rehabilitation system to be reliably safe, compact, and silent. To meet these needs, we have developed a soft metal hydride (MH) actuator utilizing the property of a hydrogen storage alloy for a part of the rehabilitation system.

The soft MH actuator consists of a soft bellows made from laminated aluminum film (PE/Al/PET, 0.1 mm in thickness) as an end effector, a container of a hydrogen storage alloy as a source of bellows motion, and a thermoelectric device such as a Peltier device for temperature control (Figure 1). A hydrogen storage alloy can reversibly absorb and release a large amount of hydrogen gas by thermal control, i.e. cooling for absorption of hydrogen and heating for releasing hydrogen from the hydride (Figure 2(a)). By converting this reversible chemical reaction into bellows stroke due to the inner hydrogen pressure change, the soft MH actuator can generate high force by a compact device and realize silent operation and
Methods: Using a robotic system, 5 controlled flexion/extension motions are employed at progressively faster speeds to collect biomechanical resistive force, position, and time data in real time. Motions are performed in the individual's sagittal plane similar to functional motions of raising an object to their head or face. A linearly separable model quantifies the velocity dependent component of resistance and statistical model demonstrates the effect MAS scores have on the new velocity dependent resistance metric. This study considered healthy controls (n = 44) and individuals with an acquired brain injury receiving treatment for spasticity (n = 39). To determine the best representation, the quantitative spasticity metric was calculated once with flexion data, once with extension data, and a final time with data from both motions.

Results: The MAS, while augmented with an additional value to indicate healthy controls, was found to be significantly effect the metric calculated from both flexion and extension motions. This was true for both MAS bicep and tricep scores. Table 1 lists fixed effects for each of the 4 models.

<table>
<thead>
<tr>
<th>Effect</th>
<th>F</th>
<th>P</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAS Bicep (Flexion/Extension)</td>
<td>16.25</td>
<td>&lt;0.0001</td>
</tr>
<tr>
<td>MAS Tricep (Flexion/Extension)</td>
<td>11.55</td>
<td>&lt;0.0001</td>
</tr>
<tr>
<td>Extension Only Data</td>
<td>1.99</td>
<td>0.0987</td>
</tr>
<tr>
<td>Flexion Only Data</td>
<td>5.19</td>
<td>0.0008</td>
</tr>
</tbody>
</table>

The metric can also distinguish between the high MAS scores (MAS 2, 3) and low MAS scores (healthy controls, MAS 0, 1) with values that were statistically significantly different.

Discussion/Conclusions: MAS bicep/ tricep scores demonstrated effects on the quantitative spasticity metric. The strongest relationship was determined for metrics calculated from both flexion and extension motions together. Flexion only calculations also found that MAS had a direct effect, whereas it approached significance with extension data. More studies and data is required to determine if a stronger relationship is achievable. The robot’s controlled and varied speed motions allowed for a calculation of a velocity dependent effect to quantify spasticity. These values are determined only from biomechanical data directly relatable to the MAS scale. This data can potentially aid clinicians in making treatment decisions and measuring progress or changes in spasticity.
SP052 - Functional Neuroimaging and Neuronavigation

SP052.1 - From human neuron to human brain: Neurosurgical contributions to understanding the brain
Author(s): Taufik Valiante
Director Of The Surgical Epilepsy Program, Krembil Neuroscience Center, Toronto/ON/CANADA

In this talk I will review neurosurgical contributions to understanding the human brain, particularly in the context of surgery for epilepsy and movement disorders. I will review early studies that have led to the understanding of localized cortical function, which formed the basis of initial attempts at understanding information processing within the brain. I will then describe ongoing work using electrocorticography and single unit recordings to elucidate fundamental human brain function including memory, attention, and language. The investigations that I will review will span many levels of investigations, from the activity of single human cortical neurons, to small cortical microcircuits, and then up to large scale integration – largely as a byproduct of the clinical care afforded to people with epilepsy. I will conclude by attempting to outline the limitations of current technologies to record from and control the human brain.

SP052.2 - Modulation of event-related desynchronization and synchronization during right finger flexion in patients with Amyotrophic Lateral Sclerosis
Author(s): Nataša Bizovičar
University Rehabilitation Institute of Republic of Slovenia, Ljubljana/ SLOVENIA

Introduction
Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder with signs of upper and lower motor neuron degeneration. Potential electroencephalographic (EEG) methods for studying upper motor neuron and other cortical motor functions during the preparation and execution of volitional movements are so-called event-related desynchronization (ERD) and synchronization (ERS). ERD is a relative EEG power decrease pre- and during motor activity and is described as an electrophysiological correlate of an activated cortical network. ERS is a relative EEG power increase after termination of the movement and is an electrophysiological correlate of cortical areas at rest. The brain has the capacity to change the architecture of the neural networks during learning or as a response to injury. Diseases that affect neuronal networks such as ALS could have an impact on the change in absolute and relative EEG spectral power, its topography and time course. Our aim was to study ERD/ERS related to finger flexion in patients with ALS.

Methods
Twenty-one ALS patients (aged 54-74 years) and nineteen matched controls (aged 48-72 years) were assessed for their hand dexterity and strength, spasticity and functional rating scales. EEGs (10-20 system, 30 channels) were recorded while patients and controls performed self-paced fast right index finger flexion motor task. EEG time-frequency analysis was performed in the alpha (8-12 Hz) and beta (13-30 Hz) bands.

Results
Patients performed significantly worse on all hand function tests and had decreased hand muscle strength compared to control subjects. Latencies of the ERD beginning did not differ between the ALS patients and controls. Patients generated significantly smaller resting alpha spectral power density and lower beta ERS compared to controls. There was a larger difference in ERS between the contra- and ipsilateral brain hemispheres in the ALS group. No significant correlations between ERD/ERS and clinical measures were observed.

Conclusions
There are different morphological and functional changes in the brain of ALS patients described in the literature which could explain some of the changes in ERD and ERS. The reduction of beta ERS could result from the loss of pyramidal cortical neurons and asymmetry of ERS in patients with ALS compared to controls could be the result of interhemispheric corticomotor network degeneration in ALS.

SP052.3 - Functional connectivity patterns associated with swallowing of fluids with various viscosity
Author(s): Iva Jestrovic1, James L. Coyle2, Ervin Sejdic1
1Department Of Electrical And Computer Engineering, University of Pittsburgh, Pittsburgh/PA/UNITED STATES OF AMERICA, 2Department Of Communications Science And Disorders, University of Pittsburgh, Pittsburgh/PA/UNITED STATES OF AMERICA

Thickened dietary fluids are commonly deployed to prevent ordinary thin liquids from entering the airway of patients with certain swallowing disorders. Their mechanism of action has thus far been attributed to two possible explanations. First, rheological properties of the thicker fluids, may render them less likely to elude in the poorly-closed airway during swallowing. Alternately, the thicker liquids may adhere to the pharyngeal mucosa thereby reducing their rate of flow. However the possibility that thicker liquids cause perturbations in central sensorimotor processing has not been considered or investigated. Therefore, we investigated the influence of fluid viscosity on associated swallowing brain networks. EEG signals were collected from 55 healthy adults who performed five water, five nectar-thick, and five honey-thick liquid swallows. Standard preprocessing of EEG time-series was utilized and pre-processed signals were filtered in the frequency bands of interest. Brain networks were formed using the time-frequency based synchrony measure. Results showed that increasing fluid viscosity resulted in higher clustering coefficients in all frequency bands (p<0.04) (Figure 1.A), while the characteristic path length tended to be lower in the Delta, Theta, and Alpha frequency bands (p<0.03) (Figure 1.B). Brain networks formed during swallowing of thicker liquids had higher small-world parameters in the Delta, Theta, and Alpha frequency bands (p<0.05) (Figure 1.C). These results provide intriguing possibilities regarding the effects of peripheral manipulations on central processing of swallowing sensorimotor function. Further investigations of the neural basis of dysphagia are warranted to elucidate this and related possibilities.
SP052.4 - Distribution of F-Latency (DFL) - a new nerve conduction parameter for early detection of radiculo-myelopathy

Author(s): K Siddique Rabbani
Biomedical Physics & Technology, University of Dhaka, Dhaka/BANGLADESH

Distribution of F-Latency (DFL) is a new nerve conduction parameter conceived and named by the author several years back and who has led many researchers over the period in improving the understanding of the parameter and its application in early detection of radiculo-myelopathy. The method has been found to work equally for the cervical and the lumbo-sacral regions, however bulk of the systematic work carried out so far is for the former, particularly using the median nerve. Described for the median nerve, DFL is basically a statistical distribution of latencies of F-responses obtained through electrical stimulation of the nerve at the wrist and recording of the evoked muscle responses from the Thenar muscle group at the base of the thumb. F-response is the secondary response occurring due to antidromic conduction of action potentials in the motor nerve fibres from the wrist to the spinal cord, and then through random backfiring in a few percent of cell bodies contributing to action potentials through these backfired nerve fibres. Because of random recruitment of nerve fibres with different conduction velocity values, the F-latencies due to multiple stimulations vary randomly and this has been used to advantage in DFL to get a picture of the distribution of Conduction velocity (DCV) of nerve fibres as an approximate mirror image of DFL, thus contributing to a practical method to measure DCV in a clinical setting, which was not possible earlier. It has been found by groups led by the author that for normal subjects DFL has a single sharp peak while for subjects with cervical radiculopathy (entrapment of the nerve roots near the spinal cord) or myelopathy (compression of the spinal cord due to a vertebral disc bulging or herniation) DFL has double peaks or broad peaks. Hypotheses have been put forward in explaining the causes of the observed patterns which have been verified to a great extent through MRI investigations on the same subjects. Some of the broad peaks are very close to a single peak and a special criterion has been set up, based on a learning process using MRI on the same subjects through a research carried out in Singapore, again led by the author, to identify these subtle broad peaks from single peaks. Recently improved detection has resulted from changing the bin starting values in calculating the statistical frequency distribution that result in the DFL and combining the outcomes of the two distributions. Further work has been carried out in order to assess the minimum number of F-responses needed to differentiate the patterns of DFL in radiculo-myelopathy. It has been found that about 15 F-responses are adequate to distinguish the DFL patterns in the above detection if the bin size is chosen as 2ms. Through the combined procedure, almost 80% correct prediction have been obtained through a double blind study, when evaluated using MRI. It is expected that this method of DFL would become a first line screening test in any peripheral neuropathy in the near future.

SP053 - Cardiovascular Instrumentation

SP053.1 - A Microfluidic cell culture Instrument for individual testing of therapeutics.

Author(s): Marie Keays1, Patrick A. Kiely2, Tara Dalton1

1Stokes Institute, University Of Limerick, Limerick/IRELAND, 2Department Of Life Sciences, And Materials And Surface Science Institute, University Of Limerick, Limerick/IRELAND

The realisation of personalised medicine has been the target of many multidisciplinary scientific teams. A system that can individualise patient care diagnostics has the potential to revolutionise medical treatment. Currently, drug discovery uses 2-dimensional cell culture techniques as a test to monitor the cells reactions to drugs these models have provided the platform for most toxicity and drug testing. However, the requirement of sample containers such as dishes or flasks are a limiting factor and do not lend themselves to automation. With a desire to understand and diagnose disease and infection at a patient specific and cellular level, there is a pressing need to modify procedures to facilitate multi-experimental approaches that are cost effective, automated and use small amounts of patient sample and reagents. This has encouraged us to develop a microfluidic droplet cell culture platform. The proposed system will create droplet cultures and facilitate incubation and imaging of the cultures on one platform. This system facilitates the establishment three-dimensional culture conditions that more accurately mimics natural cell conditions and cell-cell communication. The culture droplets are created in a nano-litre range and multiple unique bioreactor droplets can be prepared and analysed on one system making this a time and cost effective instrument. This system can benefit cancer diagnosis as multiple assays can be mixed with individual culture droplets. This lends itself to drug cocktail testing tested against a specific sample making this a powerful instrument in understanding cells.

SP053.2 - A Bioinspired Catheter Harnessing Gecko Adhesion and Inchworm-Like Locomotion for Targeted Drug Delivery

Author(s): Jonathan Wolfe1, Huan Qi3, Paul J.L. Ong1, Tze Tec Chong1, Denis Fichou1, Claus D. Ohl6, Joo S. Chia1, Subbu Venkatraman1, Swee H. Teoh2

1Interdisciplinary Graduate School, Nanyang Technological University, Singapore/SINGAPORE, 2Material Science And Engineering, Nanyang Technological University, Singapore/SINGAPORE, 3Cardiology Clinic, Tan Tock Seng Hospital, Singapore/SINGAPORE, 4Vascular Surgery, Singapore General Hospital, Singapore/SINGAPORE, 5School Of Physical And Mathematical Sciences, Nanyang Technological University, Singapore/SINGAPORE, 6School Of Chemical And Biological Engineering, Nanyang Technological University, Singapore/SINGAPORE

Invented more than 250 years ago, modern catheters have developed into a technological diagnostic/therapeutic medical instruments used in myriad applications such as catheterization, colonoscopy, ureteroscopy, dilating balloon and stenting. Some of the larger devices are capable of carrying sophisticated imaging and sensing modalities with robotic ultra-fine surgical instruments.

In recent years, smart-materials and advanced micro-manufacturing techniques have enabled the construction of millimeter-sized catheters capable of robotic bending and rotation, allowing catheters to maneuver deeper inside the patient’s body. However, a fundamental drawback is that catheters are pushed from the outside by the surgeon. This works well for large diameter vessels but poses many challenging issues for small diameter vessels. As the artery diameter decreases, increasing forces between the catheter and the vessel inner wall causes the catheter to buckle rather than advance. Moreover, the high friction caused by pushing the catheter, especially at curvatures, may result in life-threatening vessel injuries.

To resolve this, we have developed an alternative principle for catheter locomotion, here named SmartCat, an inchworm-inspired µ-robotic catheter that is powered by saline pressure. This self-pulling catheter is 2.5 millimeters in diameter, and can autonomously navigate the vessel at a speed of 2 cm/sec. The robots are batch-fabricated, and are thus suitable for mass production.

For safe implementation of the inchworm locomotion, hemocompatible gecko-inspired balloon clammers were developed. This gentle, reusable adhesive enables a dramatic reduction in the force required to achieve adequate vessel grip. In addition, these balloon clammers can also be used to form a close-off region for localized drug delivery.

(A) Prototype of an inchworm-robotic catheter prior to encapsulation within elastic silicone-gecko cloak, shown in (B). (C) Schematic of the inchworm locomotion principle.

SP053.3 - Covered stent with perforated membrane for treatment of peripheral atheroembolic disease

Author(s): Foad Kabinejad1, Mercedeh Kaabi Nezhadian2, Fangsen Cui1, Pei Ho1, Hwa Liang Leo2

1Department Of Surgery, National University of Singapore, Singapore/SINGAPORE, 2Department Of Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE, 3Engineering Mechanics, Institute of High Performance Computing, A*STAR, Singapore/SINGAPORE

We have recently developed a novel stent membrane design for covered stents that prevents emboli while preserving the side-branch flows. Our earlier in vitro studies in models of carotid arteries have shown that this novel design can maintain more than 83% of the original external carotid artery (ECA) branch flow and has the potential to considerably reduce the chance of emboli release as compared to bare metal stents. In the present study, the application of this novel stent membrane design in the treatment of atheroembolic disease in peripheral arteries is investigated. The novel stent design has been tested in a PDMS model of superficial femoral artery (SFA) and its performance has been evaluated in vitro under physiological pulsatile flow condition, utilizing flow visualization (dye injection), and particle image velocimetry (PIV) techniques. These evaluations include the assessment of emboli prevention capability, side-branch flow preservation, and influence on the branch flow pattern and velocity field.
The novel covered stent demonstrated significant emboli prevention capability, and the flow in the side branches was smooth and uniform. This study demonstrated the potential of this novel covered stent design for the treatment of atheroembolic disease in peripheral arteries. However, further in vivo investigations of biological effects and mechanical performance of this covered stent design is warranted.

SP053.4 - Nanostructuring Carbon Fibre Probes for Use in Central Venous Catheters

Author(s): Jolene Mchugh1, Meixian Li2, Marco F. Cardosi3, James Davis1 1Nibec, School Of Engineering, University of Ulster, Newtownabbey/UNITED KINGDOM, 2College Of Chemistry And Molecular Engineering, Peking University, Beijing/CHINA, 3Lifescan Scotland Ltd, Inverness/UNITED KINGDOM

Central venous catheters (CVCs) and peripherally inserted central catheters (PICC) are vital access lines through which to deliver life preserving agents whether nutritional or chemotherapeutic. Remedial treatment could be employed that would enhance the communication has sought to investigate the design of a probe that would provide an early warning signal in changes to the localised pH at the electrode and thus it could be envisaged that the probe would provide an early warning signal that bacterial colonisation and biofilm formation of the line will result in infection which can often necessitate the complete removal of the line to prevent re-infection.

While there has been extensive research into the development of antimicrobial materials to minimise biofilm formation, there are no point of care diagnostics available to provide an early warning for the onset of infection. In most cases, infection is only detected once gross symptoms (typically fever and rigor) appear and has traditionally relied on the expertise and vigilance of the healthcare staff. As most CVC lines are maintained by outpatients, there can be obvious reluctance to present a false positive, the conditions can be missed and thus it could be envisaged that the probe would provide an early warning signal that bacterial colonisation and biofilm formation of the line will result in infection which can often necessitate the complete removal of the line to prevent re-infection.

The processing algorithm developed and applied to the RF defibrillator voltage and current waveforms were digitally recorded at 250 kHz sampling frequency using a digital oscilloscope (Tektronix TDS 3014B) and a current probe (Fluke 80i-110s) during internal cardioversion of patients with persistent AF using a novel low-tilt rectilinear waveform (generated by a radiofrequency defibrillator device) following a step up energy protocol (50V to 300V in 50V steps). However, typically, the recorded signals are inherently corrupted by electrical noise. The objective of this work was to investigate if it was possible to develop an algorithm, using digital signal processing (DSP) in the MATLAB environment, to denoise the AF defibrillation voltage and current waveforms by applying spectral analysis and digital filtering techniques. Specifically, the MATLAB algorithm was developed to automatically handle the large data files recorded during defibrillation therapy. Patient number and case number were used to automate loading of the associated defibrillation voltage and current waveforms and deduce the sampling frequency; based on a-priori rectilinear pulse width (12ms). The algorithm is designed to then select the desired waveform segment (part of the rectilinear signal at time between 2ms and 10ms) and denoises, generates and plots the filtered waveforms. Finally, the algorithm calculates the dynamic resistance (ICl) and present associated parameters.

Results: Analysing the spectrum of the processed rectilinear waveform signals enabled finding the most appropriate normalized cutoff frequency estimation. The study results provided this being between 0.01 and 0.02 (normalised frequency), which corresponds to 1125Hz - 2250Hz. The evaluation results also indicated that Hanning windowing was more appropriate than Blackman windowing in the spectral analysis preservation of the rectilinear waveform signals. Furthermore, noise reduction of these signals using a 7th order Butterworth filter design was found to be more efficacious in denoising than a 200 order FIR digital filter.

Conclusion: The processing algorithm developed and applied to RF defibrillator waveforms was effective for denoising voltage and current signals. This provides a useful tool for studying large number of patient cases in the characterisation of intra-cardiac impedance and its potential relation to other factors such as the outcome of cardioversion treatment and defibrillation energy threshold.
SP054.2 - The Historical Role of Women in Medical Physics

Author(s): Magdalena Stoeva1, Virginia Tsapakis2, Simone Kodlu- lovich3

1IOMP Medical Physics World, York/UNITED KINGDOM, 2Konstantopoulo General Hospital, Athens/GREECE, 3Asociación Latino- americana de Física Médica (ALFIM), Brazil/BRAZIL

Women have always played a key role in the development of science. The first recorded information for women scientists dates back to over 10-20 centuries BC. Leading women scientists and philosophers during the antiquity have contributed towards the development of various scientific branches - Enheduanna (Sumerian astronomer), Agamede (ancient Greek physician), Merit Ptah (Egyptian physician), Tapputi-Belatekallim (Babylon chemist).

Although for centuries the scientific world was dominated by men, there are many gifted women who made key discoveries, inventions or overall scientific contributions. Whilst discussing the role of women in science, this is indisputably dominated by Marie Skłodowska-Curie – the brilliant physicist and chemist, the first woman to win a Nobel Prize, the first person to win two Nobel Prizes and the only person to win Nobel Prizes in multiple scientific disciplines.

Many other brilliant women have made their contribution to science – some of them with a direct relation to Medical Physics - Irène Joliot-Curie, Goepert-Mayer, Rosalyn S. Yallow, Harriett Brooks, Chien-Shiung Wu.

To mark the 50th Anniversary of the IOMP, national and regional medical physics organizations nominated medical physicists and other closely related professionals who have made outstanding contributions to the advancement of medical physics and healthcare through research, clinical developments, education and training activities, service development, and to professional matters over the last 50 years. Women medical physicists have been included in this Outstanding Contributions list as recognition for their devotion and contributions to Medical Physics - Penelope Allisy-Roberts, Carri-dad Borras, Maryellen L. Giger, Anchali Krisanachinda.

The trends in the contemporary scientific and working environment and women's dedication to science and practical application of Medical Physics lead to the formation of a number of women scientific and professional societies dedicated to the advancement of Medical Physics.

SP054.4 - Women in Medical Physics; current status in Australia and New Zealand.

Author(s): Eva Bezak

Australasian College of Physical Scientists and Engineers in Medici- cine (ACPSEM), Adelaide/ AUSTRALIA

According to the recent data by Australian Institute of Physics, Aus- tralian schoolgirls still prefer life sciences to physical sciences with a 2:1 ratio. This worsens at university to about 4:1. The proportion of women in senior science positions is improving at just 1 per cent per annum, and even going backwards at lower levels.

In the specific case of medical physics, in Australia and New Zea- land, there have been some positive developments in enrolment of women into medical physics training and females now account for 30% of trainee medical physicists. This is can be considered an achievement considering that 15-20 years ago many departments would not have any or only a few female medical physicists.

However, there is still underrepresentation of women at senior roles and consequently a potential lack of role models for women earlier in their career. There is also a lack of suitable part time positions (es- pecially at senior levels) for women who would like to balance family and work commitments.

Additionally, while the public service is generally accommodating for working mothers, private practice centres can be a different story (long hours, lots of travel). As the ratio of private to public radiation oncology services increases it may result in a more difficult environ- ment for women and there may also be a pronounced gender bias in recruitment.

In conclusion, more work needs to be done mentor and support young women into sustainable careers in the physical sciences and engineering, including medical physics and biomedical engineering. Strategies need to be developed that will allow women success- fully balance their family and work commitments both in public and private sectors.
SP055 - Cellular & Molecular Mechanics

SP055.1 - Neurite outgrowth induced by shock waves

Author(s): Youn Kihwan1, Akira Tsukamoto2, Akihumi Furuichi3, Keichi Nakagawa3, Takegiro Ando1, Etsuko Kobayashi1, Takashi Ushida4, Ichiro Sakuma1
1Precision Engineering, The University of Tokyo, Tokyo/JAPAN, 2Department Of Applied Physics, National Defense Academy of Japan, Yokosuka/JAPAN, 3Department Of Chemistry, The University of Tokyo, Tokyo/JAPAN, 4Department Of Mechanical Engineering, The University of Tokyo, Tokyo/JAPAN

Neurite outgrowth is one of important factors to restore neurodegenerative diseases, such as Parkinson’s disease and Alzheimer’s disease. One way to stimulate the neurite outgrowth is mechanical stimulation. For example, mechanical stretches were demonstrated to stimulate the neurite outgrowth [1]. Although mechanical stimulations are expected to be superior in treatment targeting, minimally invasive way of mechanical stimulation is required for realizing medical applications. Shock wave is one of the noninvasive ways to introduce mechanical stimulations. In addition with Extracorporeal Shock Wave Therapy (ESWT), recent studies demonstrated that shock wave could stimulate revascularization noninvasively [2]. In this research, we hypothesized that shock wave irradiation could stimulate neurite outgrowth. To verify the hypothesis, PC12 cells, a cell line of pheochromocytoma, were irradiated with shock waves. Before shock wave irradiations, PC12 cells were cultured with DMEM supplemented with 10% FBS, 5% HS, 1% L-glutamine and 30ng/ml NGF for 2days. After that, shock waves were irradiated 10 times/day for 6 days. Peak pressure of shock waves was 3MPa and irradiation frequency was 1Hz. Neurite outgrowth was quantified with NeuronJ (ImageJ add-on software) by measuring the length of selected neurites which were longer than cell bodies. As a result, neurite outgrowth was stimulated with shock wave irradiations on PC12 cells (Fig. 1(a), Fig.1(b)). With the shock wave stimulation, average length of neurites reached 268μm±95μm compared to 213μm±88μm in control cells without shock wave irradiations (Fig. 1(c), ***p<0.001). Through this result, we knew that neurite extension can be promoted by shockwave. Although it was revealed that shock wave could stimulate neurite outgrowth in PC12 cells, further study is required to clarify the mechanical and biological mechanisms by which shock waves promote neurite outgrowth.

SP055.3 - Collagen fibrils from overloaded tendons show sites of discrete plasticity and overall perturbation in molecular packing

Author(s): Samuel Baldwin1, Laurent Kreplak2, J. Michael Lee3
1Physics And Atmospheric Science, Dalhousie University, halifax/NS/CANADA, 2Physics And Atmospheric Science, Dalhousie University, Halifax/NS/CANADA, 3School Of Biomedical Engineering, Dalhousie University, Halifax/NS/CANADA

Tendons show the ability to resist rupture and to retain partial mechanical function after overload, characteristics which may have evolutionary importance. Understanding the origins of such intrinsic structural toughness, and the mechanisms of cellular response to damage, may provide important insights into tendon trauma and its treatment. Probing the nanoscopic structure of overloaded tendon has revealed an intriguing candidate mechanism. This process, termed discrete plasticity, was revealed by scanning electron microscopy to involve periodic kink deformations along individual collagen fibrils within overloaded tendon [1]. The influence of discrete plasticity on thermal stability of collagen, its enzymatic susceptibility, and its cellular response have been studied; however, the localized, nanoscale mechanical properties of the kinked structure remain unknown [2,3].

Previous work with atomic force microscopy on hydrated collagen fibrils has demonstrated the ability of peak force quantitative nanomechanical mapping as a probe of molecular density, mapping lateral packing variations along individual collagen fibrils by measuring compression modulus at tip velocities above 100μm/s [4]. Applying this methodology to fibrils displaying discrete plasticity resulted in high resolution maps of the localized molecular density of kinked structures formed along overloaded collagen fibrils (Figure 1.A). The resulting data demonstrated that the topologically discrete kinks are coupled with a decrease in molecular density along the entire fibril. This decrease can be attributed to an increased uptake of water when compared to control fibrils. High resolution maps of the same fibrils in a dehydrated state clearly demonstrate retention of D-banding axial packing structure throughout the kinked fibril with the exception of periodic fault lines at kink locations (Figure 1, B). This suggests that the axial register of collagen molecules, characteristic of collagen fibrils, is retained in regions spanning the kinked structures of the discrete plasticity phenomenon in collagen.

Figure 1: High resolution maps of the same kinked fibril representing (A) its compression modulus in the hydrated state and (B) its height in the dehydrated state.

SP055.4 - Mechanobiology of Hepatic Cells and Engineered Construction of Liver

Author(s): Mian Long
Center For Biomechanics And Bioengineering, Institute of Mechanics, Chinese Academy of Sciences, Beijing/CHINA

Liver microcirculation is unique due to its complicated structure of sinusoidal nodes, in which multiple types of hepatic and/or hematopoietic cells interact with each other under blood flow in a three-dimensional (3D) environment. Adhesion of flowing leukocytes to liver sinusoidal endothelial cells (LSECs) or Kupffer cells (KCs) is crucial in liver immune responses. While it is known that two b2 integrins LFA-1 and Mac-1 play distinct roles in the most of organ-specific microcirculations, Mac-1 seems to be predominant in neutrophil (PMN) adhesion and crawling in localized inflammation while the role of LFA-1 is controversial in liver. We first compared the binding kinetics of LFA-1 and Mac-1 to ICAM-1s on mouse LSECs or KCs and found that the binding kinetics between these two integrin molecules is different when ICAM-1s were expressed on distinct cells, supporting that Mac-1 predominantly mediates the adhesion between leukocytes and LSECs and KCs. Next, we tested the flow-induced crawling of mouse PMNs on LSEC monolayer and observed that PMNs tend to migrate along the direction of shear flow and yield high crawling velocity and moving displacement than those under static condition, mainly mediated by LFA-1. Then, we also quantified the impact of substrate stiffness and microtopography on hepatic differentiation of stem cells using 3D in vitro sinusoidal model and engineered liver bioreactor, in which physiologically-mimicking microenvironment is critical for implementing hepatic functions. This work provides an insight for quantifying the intrinsic binding kinetics and the blood flow-induced crawling features of hepatic cells and proposes a novel 3D supporting system for liver function, from a viewpoint of mechanobiology.

SP055.5 - Modelling and Understanding Normal Pressure Hydrocephalus

Author(s): Christine Goffin1, Anne Holterhoff1, Steffen Leonhardt2, Klaus Rademacher1
1Chair Of Medical Engineering, RWTH Aachen University, Aachen/ GERMANY, 2Chair Of Medical Information Technology, RWTH Aachen University, Aachen/GERMANY

Up to 10% of all dementia patients may actually suffer from Normal Pressure Hydrocephalus (NPH), a disease whose pathogenesis is not yet understood. The ventricles enlarge in this particular form of hydrocephalus, although the mean intracranial pressure (ICP) is not elevated. In this paper, the two main biomechanical hypotheses for the formation of NPH are examined by critically reviewing biomechanical models investigating the onset of NPH: 1) A transmantle pressure gradient between ventricles and subarachnoid space (SAS) widens the ventricular space mechanically, stresses the ventricular walls and causes edema leading to tissue damage. 2) Disturbed dynamics caused either by reduced compliance, vascular disease, malabsorption or obstructions of cerebrospinal fluid (CSF) pathways cause tissue damage. The different models are analyzed and contrasted with clinical findings in order to summon what could be gained by biomechanical model based analysis. It is the goal of this article to identify open questions that can be answered by biomechanical models.
SP055.6 - Osteolytic tumour involvement modifies characteristics of Collagen-I within the vertebral bone matrix impacting mechanical behaviour

Author(s): Mikhail V. Burke, Cari Whyne, Thomas Willett

University of Toronto, Toronto/CANADA

Vertebral mechanical integrity is diminished in the presence of metastatic disease. Modelling of the biomechanical behaviour of metastatically involved (MI) bones, however, has to date focused on structural changes alone, without accounting for the potential impact of alterations in bone quality (tissue level changes). More specifically, changes in the organic components of the bone matrix. This study aims to characterize vertebral structure, modifications in primary organic constituent of bone: Collagen-I and mechanical consequences due to the presence of osteolytic metastasis.

Osteolytic (n=8) vertebral metastases were generated in an athymic rat model via intracardiac injection of HeLa cancer cells. μCT imaging was used to quantify the stereologic distribution of mineralized tissue. Transmission electron microscopy (TEM) and high power liquid chromatography (HPLC) were used to assess the organic phase of bone. And finally, mechanical testing of spinal motion segments was conducted through stepwise loading (axial compression) in combination with time-lapsed μCT imaging.

Osteolytic tumour involvement (TI) caused an increase in trabecular spacing; and a decrease in trabecular number, spacing and tissue & bone mineral density compared to healthy controls. This indicates that osteolytic involvement reduced both the amount of trabecular bone and the mineral density of the remaining bone.

TEM revealed fibril misorientation in osteolytic specimens and a decrease in the fibril diameter of the collagen fibril matrix on the surface of bone adjacent to tumour lesions. HPLC analysis showed no impact of osteolytic disease on the collagen content in bone, but revealed a decrease in specific enzymatic crosslinks (deoxy-pyridinoline) and an increase in non-enzymatic crosslinks (pentosidine) indicative of the operation of reactive oxygen species produced by tumour presence and the resulting oxidative stress.

Osteolytic motion segments when loaded to failure also showed reduced peak failure loads and stiffness with bone failure being focal in nature and not causing major deformation throughout the entire structure with continued loading.

Osteolytic tumour involvement both reduced bone mineral density and caused changes within the organic phase of bone, negatively impacting the mechanical behaviour of bone. Identifying changes in the material phase of (MI) bone and establishing correlations between such changes and the material & mechanical properties/behaviour is critical for the establishment of a fundamental knowledge base needed for modelling and evaluating fracture risk and guiding future treatment options.

SP056 - Image Guided RT: Part 2

SP056.1 - Imaging Dose and Dose Pattern in Image-guided Radiotherapy of Cancers

Author(s): Li Zhou1, Sen Bai1, Yibao Zhang2, Xin Ming3, Ying Zhang4, Jun Deng5

1Center For Radiation And Technology, Cancer Center, West China Hospital, Sichuan University, Chengdu/CHINA, 2Key Laboratory Of Carcinogenesis And Translational Research (ministry Of Education), Department Of Radiotherapy, Peking University Cancer Hospital & Institute, Beijing/CHINA, 3Department Of Biomedical Engineering, Tianjin University, Tianjin/CHINA, 4Department Of Therapeutic Radiology, Yale University, New Haven/CT/UNITED STATES OF AMERICA

Purpose: To systematically evaluate cumulative doses to organs-at-risk from various radiological imaging procedures in image-guided radiotherapy (IGRT) and corresponding dose patterns in a large cohort of cancer patients treated at one institution in past four-and-half years.

Methods and Materials: With IRB approval, 4832 cancer patients treated at our institution during past four-and-half years were collected with their gender, age, circumference as well as all the radiological imaging procedures performed, which may include computed tomography (CT), kilo-voltage portal imaging (kVPI), megavoltage portal imaging (MVPI) and kilovoltage cone-beam computed tomography (kVCBCT). Correlations between patient’s size and organ dose were first established via Monte Carlo dose calculations in patient anatomy, and then used for patient-specific organ dose estimation. BEIR VII models were employed for radiation-induced relative risk estimation based on one’s gender, age and radiation dose.

Results: There were a total of 5298, 24173, 30605, 35110, 37509 and 9322 procedures performed on 202, 938, 1056, 1117, 1165 and 354 patients in 2009, 2010, 2011, 2012, 2013 and 2014, respectively. Among them, 3.6%, 14.2%, 23.8 and 56.4% were from CT, kVCBCT, MVPI and kVPI, respectively. In total, 92.8%, 90.3% and 68.5% of patients received 30 Gy or less doses to brain, lungs and RBM, respectively. Yet, 80 Gy or more doses were deposited to brain, lungs and RBM in 273 small-sized patients (maximum 136, 278 and 267 cGy, respectively), due largely to repetitive procedures and non-personalized imaging settings.

Conclusions: The cumulative imaging doses and associated cancer risks from multi-imaging procedures were highly patient-specific and lesion-dependent, with much higher doses and risks in pediatric patients. With personalized dose estimation, the impact of radiological imaging procedures can be accounted for effectively for clinical treatment planning and decision-making. This study indicated a pressing need for personalized imaging to maximize its clinical benefits while reducing associated cancer risks.
Results: The mean RSE for 10 patients are shown in Fig 1b. A minimum error of approximately 1 mm occurred between C3 and C4 and increased for C5-C7. The largest error was observed on Pt #1 (5.6 mm at C7), which was in part due to in-plane rotations, not compensated for during treatment. The estimated cumulative Dmax and their relative increase from plan (ΔDmax) are presented in Fig 1c and Fig 1d respectively. For five patients, the delivered Dmax exceeded 45 Gy with a maximum of 47.6 Gy (Fig 1c). The largest increase of 13.4% (5.6 Gy) was observed in Pt #1 due to the largest RSE.

Discussions and summary: In regard to the cumulative dose, 5 of 10 patients had the Dmax between 45 and 50 Gy, which exceeded the dose constraint of 45 Gy. Structures beyond the C spine were not included in this study due to the limited length of CBCT images. These results indicate that caution must be exercised during daily positioning of patients with head and neck cancers. Proper PRV margins must be developed to ensure that the maximum cord doses from setup errors, such as flexion, are within the maximum dose constraint over the entire course of treatment. Further research in this area is warranted.

SP056.2 - Residual errors and dosimetric consequences related to the spinal cord in head and neck radiotherapy

Author(s): Jinkoo Kim, Chang Liu, Akila Kumarasiri, Robert Rusnac, Correen Fraser, Indrin J. Chetty, Farzan Siddiqui

Radiation Oncology, Henry Ford Health System, Detroit/MI/UNITED STATES OF AMERICA

Purpose: To estimate daily setup errors related to the cervical spinal cord and associated dosimetric consequences during head and neck radiotherapy.

Methods and Materials: Ten oropharyngeal cancer patients (stage IV, squamous cell carcinoma) were retrospectively selected. All patients were treated with volumetric modulated arc therapy (VMAT) with two full gantry rotations. A total dose of 60-70 Gy was delivered in 30-35 fractions. The spinal cord dose was constrained to be less than 45 Gy using an expansion margin of 5 mm (PRV). Cone-beam CT (CBCT) imaging was used for daily patient setup, and patients were immobilized with a thermoplastic mask.

In order to measure quantities at each spinal cord level, the spinal cord contours were split into “level” segments (Fig 1a). For the calculation of cumulative dose to cords, 1) dose distributions were calculated on all CBCT images using the original treatment plan, and 2) transferred and accumulated in the corresponding planning CT space using a deformable image registration algorithm. The maximum doses (Dmax) in the segmented cord volumes were reported. In addition, the residual setup errors (RSE) were calculated by averaging the deformation vectors in the level segments.

SP056.3 - An automatic dosimetric and geometric tracking system for head and neck adaptive radiotherapy

Author(s): Chang Liu1, Akila Kumarasiri1, Mona Kamal1, Mikhail Chetvertkov2, J. James Gordon1, Hualiang Zhong1, Farzan Siddiqui1, Indrin J. Chetty1, Jinkoo Kim1

1Radiation Oncology, Henry Ford Health System, Detroit/MI/UNITED STATES OF AMERICA, 2Medical Physics, Wayne State University, Detroit/MI/UNITED STATES OF AMERICA

Purpose: The ability to track geometric and dosimetric changes in tumors and organs at risk, over the course of fractionated radiotherapy is essential for proper adaptive radiation therapy (ART). To that end, we have developed an ART engine that integrates clinical processes and groups (Fig 1). The ART engine is fully autonomous and consists of several modules; data import/export, automatic dose calculation, deformable image registration (DIR), interactive DIR/report review, and messaging. 1) The data import/export module transfers data between the Varian Eclipse TPS and the ART database, implemented via the Varian DICOM DB daemon and the Eclipse Scripting API (ESAPI). 2) The automatic dose calculation module calculates the dose of the day (DoD) on CBCT images. 3) The calculated DoD is then warped via the DIR module to the planning CT for cumula-
SP056.4 - Morphological Analysis of Tumor Regression and Its Impact on Deformable Image Registration for Adaptive Radiotherapy of Lung Cancer Patients

Radiation Oncology, Henry Ford Health System, Detroit/UNITED STATES OF AMERICA

Deformational and mass changes associated with regression of the visible tumor during the course of fractionated radiotherapy have confounded the ability to perform accurate deformable image registration, subsequently limiting the clinical implementation of adaptive radiotherapy. This study sought to investigate the impact of tumor regression on the accuracy of deformable image registrations (DIR) and then to find a solution to improve the performance of DIR for treatment of lung cancer patients. Specifically, daily cone-beam computed tomography (CBCT) images were acquired from three locally advanced NSCLC patients. DIRs were performed from fractions 1, 10, and 20 to fraction 25 using a B-Spline-based algorithm implemented within the VelocityAI platform. To improve the accuracy of the B-Spline-based registrations in the region of regressing tumors, a hybrid finite element method (FEM) was developed with a mesh defined in a bounding box surrounding the tumor in the target image. The constraints of the FEM model were derived from the displacements generated by the B-Spline registrations. Using the displacement vector fields (DVFs) of the B-Spline and hybrid registrations, the source images were warped to their targets. The accuracies of the two registration algorithms were evaluated, using landmark points identified on both the source and target images, as well as quantitative analysis of the generated DVFs. For the three patients, average tumor volumes were reduced by 53% between fraction 1 and fraction 25. Comparison of landmark points showed that the mean errors of the FEM-based hybrid registrations were 1.4, 1.6, and 1.7 mm for the three patients. The average displacement differences between the B-Spline and FEM-hybrid registrations for the three patients were 4.8, 6.2 and 3.9 mm with a maximum of 15 mm for patient 2. Lung tissue does not move consistently with the shrinking tumor. The more the tumor regresses, the larger the B-Spline registration error in the tumor region. The proposed hybrid method that consists of the intensity-based image registration and mechanics-based tissue modeling to correct geometric changes induced by anatomical deformation and tumor regression, respectively, may have the potential to improve the quality of adaptive radiation therapy for lung cancer patients.
**SP056.5 - Assessment of a 4D-CBCT system for managing respiratory motion in Radiotherapy**

**Author(s): Yudy Ascencion¹, Rodolfo Alfonso¹, Raul Argota², Haydee Linares³**

¹Nuclear Engineering, High Institute for Applied Technologies and Sciences (InSTEC), Havana/CUBA, ²Radiotherapy, Institute of Oncology and Radiobiology, Havana/CUBA

**Abstract:**

Four-dimensional image guidance for correcting baseline shifts of tumors, affected by respiratory motion, has become available in the motion management option implemented inside the Elekta’s Cone Beam Computed Tomography (CBCT) system. Using this 4D-CBCT is particularly relevant when the tumor is localized in thorax, allowing reduction of target margins. The aim of this study was to design and test a procedure for appraising the performance of a 4D-CBCT system, intended to improve accuracy in treatment delivery of Stereotactic Body Radiation Therapy (SBRT).

**Material and Methods:**

Volumetric reconstruction accuracy (VRA), target displacement accuracy (TDA) and patient positioning accuracy (PPA), resulting from the use of the studied 4D-CBCT system (Elekta XVI VolumeView SymmetryTM), was evaluated under different acquisition and reconstruction conditions. A CIRS008A Dynamic Thorax Phantom was employed, which allows simulation of a breathing human torso, including insertion of «tumors» of different sizes and shapes. Static and dynamic phantom scans were performed with the CBCT system in 3D and 4D (SymmetryTM) modes. Resource sparing settings were additionally tested, decreasing the number of reconstructed phases per breathing cycle (PPBC), increasing the gantry speed (GS) or reducing image resolution (IR). The impact on accuracy of these modifications was investigated.

**Results:**

The acquisition of 3D-CBCT with static phantom was used as baseline for some parameters, as VRA and PPA. The results obtained with the CIRS008A phantom (with 2 cm spherical tumor insert) are presented in table 1.

Using the default settings suggested by the manufacturer (No. 3 in table 1), the 4D-CBCT ensures an adequate VRA, compared with the conventional 3D-CBCT (±1mm). Reduction of PPBC from 10 to 5 significantly degraded the VRA, emphasized when the GS is increased. An IR increment does not produce substantial benefits in VRA. A preset “shark fin” waveform with known amplitude in the three main axis was used for analysis for the TDA, evidencing that setting 7 guarantees optimal TDA with faster data acquisition and processing and much less data storage requirement.

**Conclusions:**

The methodology implemented allowed to verify the capability of theSymmetryTM tool for optimizing target localization in dynamic conditions, including internal margin assessment, which is not considered in the XVI acceptance testing protocol. It could serve as comprehensive guidance for commissioning and optimizing 4D-CBCT systems intended for IGRT, in low resource environments.

SP057.1 - Sensitivity of VMAT patient specific QC devices to linac calibration errors

**Author(s):** Eduard Gershkevitsh, Mihhail Gershkevitsh

Radiotherapy, North Estonia Medical Centre, Tallinn/ESTONIA

**Purpose:** The aim of this study was to investigate the impact of linear accelerator calibration (dose and MLC) errors on 3D gamma analyses performed by four different devices for VMAT patient specific QC.

**Methods and Material:** Different calibration errors were introduced to the Linac and fifteen different VMAT plans (5 prostate, 5 pelvic nodes, 5 head & neck) were measured. The errors include 1) addition of 1.6 mm MLC leaf gap to all leaves; 2) shift of both MLC banks by 1.6 mm in one direction; 3) increasing dose output by 3%, decreasing dose output by 3%. For all conditions the treatment plans were measured with ArcCheck (Sun Nuclear), Octavius 4D (PTW Freiburg), Delta 4 (Scandidos) and Compass (IBA Dosimetry) devices. 3D gamma evaluation using local and global settings were performed. The original measurement (without intentional errors) results were than compared to those with errors and the ability of devices and used metrics to detect the errors were analyzed. Student’s T-test was used to evaluate the differences at 0.05 level.

**Results:** In total 300 measurements were made. The best results for the devices were achieved using 3D gamma index with 2% local dose difference and 2 mm distance to agreement criteria which identified most of the introduced errors (Figure 1). ArcCheck was able to detect 50% of the errors introduced in the present study using 3D gamma metrics while other detectors were able to do so for more than 70%. Compass was able to pick-up the most errors while performing 3D gamma evaluation only on PTV volumes. Octavius 4D was not able to detect the introduced gap to MLC for the pelvic nodes plans, whereas ArcCheck and Compass were not able to do so for the prostate plans.

**Conclusion:** 3D gamma analyses with 2%/2mm criteria identified more errors than 3%/3mm. Different devices can detect various errors and sensitivity to the introduced errors depends on the anatomical site/modulation complexity. Since not all errors were detected by the tested devices using 3D gamma index the alternative metrics would have to be employed to increase the sensitivity.

*Figure 1. Percentage of detected errors with 3D gamma metrics*
SP057.3 - Development of a Radiochromic Film Dosimetry Imaging System

Author(s): Kevin M. Alexander1, Ajay Rajaram2, L John Schreiner1
1Department Of Physics, Engineering Physics And Astronomy, Queen's University, Kingston/CANADA, 2Department Of Medical Physics, Cancer Centre of Southeastern Ontario, Kingston/ON/ CANADA

As radiation therapy treatment modalities advance, dose deliveries for cancer treatments have become more and more complex. Due to their advanced nature, these treatments call for increasingly high spatial resolution dosimetry techniques to verify that a prescribed dose is delivered accurately and precisely. Radiochromic film dosimetry has been adopted in the clinic as a convenient option for quality assurance because it provides high resolution, two-dimensional measurements, is essentially energy independent, and is near tissue equivalent. Unfortunately, it is not always easy to use due to imaging challenges with current readout systems.

Gafchromic EBT3 film (International Specialty Products, Wayne, NJ) is typically read out using an advanced flatbed scanner. However, difficulties overcoming imaging artifacts on these scanners, related to such factors as directional dependence of the dosimetry results with respect to film orientation and non-uniform sensitivity over the scanner area, have prompted the development of strict protocols for film readout and sophisticated image correction techniques. Even with strict protocols, reliable and reproducible dosimetry can be a challenge. To overcome these challenges, a simple readout technique based on components of the Vista optical CT scanner (Modus Medical Devices, London, Canada) was investigated.

In this work, a film readout system consisting of a digital camera and diffuse light box, interfaced with computer image acquisition software has been developed and characterized for the purpose of imaging film. The optical properties of the system, light field flatness and stability, and various calibration techniques were studied and optimized.

Fils are rapidly read out by averaging 100 images in 7 seconds, producing submillimetre digitized film data with a high signal-to-noise ratio. Single channel and triple channel film readout algorithms have been implemented and applied for dose processing. Validation tests examining simple irradiations as well as more complex dose deliveries (from IMRT, VMAT, and SBRT) showed that film imaging using our imaging system is orientation independent, and that good agreement (< 1.5% dose difference) is found using single channel dosimetry methods with red light illumination in the central region (15 x 20 cm²) of the light field (see Figure). However, when films are imaged near the perimeter of the light box, large dose discrepancies can be produced due to the non-uniformity of the light field (see Figure). Studies are currently underway to improve uniformity.

Overall, this simple imaging technique shows good promise to simplify and improve on existing film dosimetry readout. Further optimization of the system is underway.

SP057.4 - Implementation of MOSFET detectors for in-vivo radiotherapy dosimetry.

Author(s): Yi Wah Eva Cheung
Medical Engineering & Physics, King's College London, London/ UNITED KINGDOM

Background: In vivo dosimetry is an essential part of radiotherapy (RT) and is recommended by national and international organisations. For patient undergoes radiotherapy for brain tumours or head and neck cancers, lens dose is concerned. Recently, ICRP review the dose to organs at risk (OARs) and reduced the lens dose limit to 50cGy. IAEA suggested that proper eye protection should be used for these patients. For patients undergo total skin electron beam therapy (TSEBT), in vivo dosimetry is important to verify the trunk dose, to ensure appropriate dose is given with sparing effect to the underneath organs. At Guy's and St. Thomas' hospital (GSTT), TLDs were employed for in vivo dosimetry, while it involves complicated pathway. MOSFET is handy and easy to use, it has been widely used in vivo dosimetry in recent years.

Methods. MOSFET characteristics including calibration factor, linearity, post irradiation stability, reproducibility, dose rate, beam angulation, beam energy, field size, temperature and attenuation effect were carried out. Phantom study was performed using MOSFET to measure the lens dose for brain tumour or head and neck cancer and trunk dose for TSEBT. Finally, clinical study was performed for lens dose measurements for two 3D conformal, two IMRT, two VMAT and three tomotherapy patients. Trunk dose measurement was performed for one TSEBT patient.

Results and Discussion. MOSFET sensitivity met the manufacturer’s specifications for linearity post irradiation stability and reproducibility. Further study is needed to verify beam angulation and temperature dependence, as our setup used was different from that of the manufacturer’s recommendations.

In phantom study, measurements by MOSFET exhibited less variation against treatment planning system (TPS) in both lens dose and trunk dose measurement (max. 2.84cGy and 5cGy respectively) compared to the TLDs (max 5.43cGy to 16.6cGy) respectively.

In real time in vivo lens dose measurement, MOSFET exhibited similar measured dose difference against TPS compared to TLD in most of the cases. It showed higher measured dose difference in a few cases, where technical or patients challenges may be encountered. The measured dose difference in lens dose between TLD and MOSFET were within 4cGy in 78% of cases. For radiotherapy treatment for brain tumour or head and neck cancer, this would contribute no more than 120cGy dose difference over a standard course of 30fractions and is within the acceptance tolerance in GSTT, which is 200cGy dose difference over the whole course of treatment.

Conclusion. The use of MOSFET for in-vivo dosimetry has some advantages and disadvantages. It is physically small and provides accurate real time measurement with simple calibration procedure. Time required for pre and post processing is minimal compared to TLDs. It serves as a good alternative for lens dose measurement in radiotherapy for patients with brain tumour or head and neck cancer. However, practical issues may need to be resolved prior to the application of MOSFET in trunk dose measurement in TSEBT.
Purpose: 1) To elucidate the clinical implementation of our offline 3D in vivo dosimetry method for daily patient-specific QA, and 2) to test a method for terminating treatment delivery if the online measured 3D dose distribution would result in a strong overdose in the patient.

Methods: Automatic 3D in vivo dose verification has been implemented in our department using a-Si EPIDs in combination with a back-projection algorithm, and is applied for almost all IMRT/VMAT and palliative treatments. Comparison of the EPID-based reconstructed and planned 3D dose distribution is done offline. In our current clinical workflow we measure the 3D in vivo dose distribution during the first fractions of a treatment. When deviations are detected, alerts are raised automatically and actions scheduled. Furthermore, a software package for online dose reconstruction has been developed, which processes portal images in real time. Hot spots are then sought in which the average cumulative reconstructed dose exceeds the average total planned dose by at least 20% and 50 cGy. The complete processing of a single portal frame, including hot spot detection, takes about 220 ms, which is faster than the frame rate of about 2.5 frames/s of the portal imager. The software was tested by irradiating an Alderson phantom with two arcs from a head-and-neck VMAT treatment when various types of serious delivery errors were introduced.

Results: 5766 treatment plans were verified in 2013; alerts were raised in 1397 cases (24%). Non-optimal implementation of our method in the clinic, and limitations of the dose reconstruction algorithm are the main sources of alerts. About 50% of the alerts during lung treatments are caused by anatomy changes, while during breast treatments about 50% of the alerts result from patient setup variation. The online dose reconstruction tests with the Alderson phantom showed that it was possible to detect hot spots in real time before dose delivery was completed. This information was able to generate a trigger to halt the linac in case of gross errors (see figure). This method would be complemented by offline dose verification to detect more subtle errors.

Conclusions: Our automatic offline verification method enables large scale clinical implementation of 3D EPID-based in vivo dose verification. A prototype online 3D dose verification tool using portal images has been successfully tested for various kinds of gross delivery errors, allowing to stop an irradiation in case of serious errors even before a full fraction is given.

Methods and Materials: Advanced test cases were conceived based on strategy proposed by TECDOC 1583, for assessing main sources of inaccuracy in dose calculations, provided the RTPS has successfully passed the conventional tests proposed by TECDOC 1583. A total of 6 test cases were designed and tested, employing three phantoms and implemented on two different RTPS.

Test case 1 (IMRT) has the purpose of verifying calculations with intensity modulated static fields. A CIRS IMRT THORAX phantom, model 002LFC was employed. Target and avoidance structures, beam arrangement and goals were adapted from the “CShape (harder)” test proposed in AAPM TG-119.

Test case 2 (highly conformed arc) is intended to verify calculations with dynamically conformed arcs. The target is a very irregular structure, which demands rapid changes of the dynamic MLC shape with the gantry angle. The same phantom as test case 1 is used.

Test case 3 (SRS-head): is used for checking calculations in small field conditions with stereotactic positioning devices and dynamically conformed arcs. A home-made skull phantom was used.

Test case 4 (SBRT-frame-based) verifies calculations with small fields in low density tissues, including positional accuracy using stereotactic body frames. The same phantom as test case 1 is used.

Test case 5 (SBRT-IGRT): similar to case 4, but using IGRT system.

Test case 6 (4D-SBRT) utilizes a dynamic thorax phantom (CIRS S008A) for evaluating dose calculation features under respiratory motion conditions.

Results and Discussion: Results of test cases are summarized in Table 1. Relative errors are compared with agreement criteria adapted from AAPM TG-119 and TECDOC 1583, considering complexity of case analyzed.
**SP057.7 - Implementation of statistical tolerance for patient specific QA and independent monitor unit calculation**

**Author(s):** Frédéric Girard  
Département De Radio-oncologie, Centre intégré de cancérologie de Laval, Laval/QC/CANADA

**Purpose:** Standard and arbitrary tolerance for patient specific QA and independent monitor unit calculation were replaced by statistical tolerance based on past clinical results. The implementation of these tolerances was evaluated over a period of two years.

**Materials and Methods:** Patient QA results were collected and analysed statistically. They included ionization chamber dose difference, ArcCHECK (Sun Nuclear Corporation, Melbourne, FL) gamma factor passing rate, and radiochromic film gamma factor passing rate. Gamma factors were calculated with 3% absolute dose and 3 mm distance thresholds. Results from the ionization chamber and the ArcCHECK were divided in different categories based on the treatment plan complexity: 3D conformal (including wedge field), forward planning step and shoot, inverse planning step and shoot and VMAT. Radiochromic film were only used in patient QA when the modulation of the treatment plan was estimated to be very high, therefore the results were not divided into categories. For electron treatment plan, the difference between the measured and calculated depth of the isodose of prescription was also included. In addition, treatment field monitor unit difference calculated by the treatment planification system and the independent system were also included in the analysis and divided into several categories: open, wedge, forward planning step and shoot, inverse planning step and shoot and VMAT. Outliers were removed from each distribution. If the distribution was normal, parametric statistics were used, otherwise non-parametric statistics were used. A first set of tolerances was define has the 95% confidence interval of the dataset (or the range for 95% of the observation for non-parametric dataset). A second set of tolerances was defined at 99%. Results that were beyond the first tolerances required an investigation but were still deemed acceptable whereas results beyond the second tolerances were unacceptable.

**Results:** These new tolerances were tested for a period of two years. In most cases, test results that fall beyond tolerances were caused by a preparation error and were easily corrected. In other cases, the errors encountered were real and significant. For example, ionization chamber measurement would sometime fall outside tolerances when a plan was highly modulated. This situation led to the improvement of our QA procedure by using a smaller chamber less prone to this error. In another situation, large differences in the depth of the prescription isodose led to the discovery of a calculation error in our independent monitor unit calculation system in some conditions. In

**Conclusions:** Proposed test cases demonstrated being very useful not only for assessing RTPS dose calculation accuracy, but as comprehensive end-to-end verification of the overall process.
some rare instances, small calibration errors of the linac were detected using these new tolerances. None of these errors would have been detected with the conventional arbitrary tolerance.

**Conclusion:** Building new tolerances based on clinic statistical results provides an increased sensitivity of the QA program to errors that may otherwise remain undetected using conventional tolerance.

**TRACK 05: DOSIMETRY AND RADIATION PROTECTION**

**SP058.1 - Destructive backscatter-based readout of polymer gel dosimeters: proof of principle**

**Author(s):** Warren G. Campbell¹, Derek M. Wells², Andrew Jirasek³

¹Physics & Astronomy, University of Victoria, Victoria/BC/CANADA, ²Physics, British Columbia Cancer Agency - Vancouver Island Centre, Victoria/BC/CANADA, ³Physics, University of British Columbia - Okanagan, Kelowna/BC/CANADA

A new method is introduced for evaluating the radiation-induced polymer distributions in polymer gel dosimeters. Destructive backscatter-based readout (DBBR) involves the careful slicing and scanning of dosimeters using dual chromatic scans (e.g., red and blue). Spectral differences in scatter attenuation coefficients cause blue light to be more likely to be scattered by polymers than red light. Comparing the intensities of backscattered red and blue photons allows one to evaluate polymer density.

Two polymer gel dosimeters were irradiated, sliced and scanned using the DBBR method. Scans of central slices in two different irradiation patterns were acquired using a flatbed scanner, and ['blue channel' – 'red channel'] images were used to measure polymer distributions. DBBR scan results were then compared against dose distributions calculated by treatment planning software, and select regions of interest (ROIs) from each scan allowed for quantitative comparison between DBBR values and dose. For comparison, reconstructions were also obtained for the same dosimeters (prior to their destruction) using a fan-beam optical computed tomography (CT) scanner.

Results demonstrate that DBBR is a feasible method for polymer gel dosimeter readout. The new method shows great potential, especially in comparison to optical CT results. The following figures are provided for this short abstract. For more details and discussion, see the full paper abstract.

![Fig. 1: Dose images for two irradiation patterns – a star pattern and two dosages of a cross pattern – are shown in (a) optical CT reconstructions, (b) TPS-calculated dose distributions, and (c) DBBR scans. Circular ROIs, 5 mm in diameter and indicated in (b), were used for DBBR-to-TPS comparisons and DBBR calibration.](image)
Fig. 2: Plots of ROI comparisons between DBBR and TPS images are shown for (a) blue and red channels, and (b) blue minus red. Plot points are means and error bars indicate ±1 standard deviation.

SP058.2 - New Detector Systems for the Dosimetry in Radiation Therapy

Author(s): Viktor Iakovenko1, Stephan Brons2, M Campbell3, O Kov- alchuk1, Xavier Llopart3, Immaculada Martinez-Rovira4, S Pospisil5, V Pugatch1, Yolanda Prezado4, Iurii Sorokin1

1High Energy Physics Department, Kiev Institute for Nuclear Research, Kiev/UKRAINE, 2Heidelberg Ion Beam Therapy Center (HIT), Heidelberg/GERMANY, 3CERN, Geneva/SWITZERLAND, 4Laboratoire D’imagerie Et Modélisation En Neurobiologie Et Cancérologie, Centre National de la Recherche Scientifique (CNRS), ORSAY/ FRANCE, 5Institute of Experimental Applied Physics (IEAP), Prague/ CZECH REPUBLIC

The main goal of radiotherapy is to deposit a high dose of ionizing radiation in a tumor while keeping the absorbed dose in the surrounding healthy tissue at a tolerable level. Current developments in radiation therapy require non-destructive beam profile monitoring devices providing dose distribution measurements and imaging in real time. For this purposes a Micro-strip Metal Detector (MMD) has been developed [1]. Physics and techniques of this detector for the dosimetry, measuring and imaging charged particles and synchrotron radiation beams are discussed. An extremely low thickness (~1 μm) of the MMD in combination with its high radiation tolerance (~100 MGy) introduces an opportunity to keep a device in the beam permanently [2]. MMD as well as metal-mode of micropixel detector TimePix have been successfully tested at the Minibeam Radiation Therapy (MBRT) setup (Bio-Medical Beamline ID17, ESRF) [3]. These detectors were explored also in recent studies at Heidelberg Heavy-Ion Therapy Center (HIT) devoted to the evaluation of the prospects of spatially fractioned hadron therapy. Hadron multi-beam structures have been created by the collimators with different shape. Holes or slits were made in aluminum, brass or tungsten (50 mm thick) samples to arrange different multi-beam structure shape (“MATRIX” or “SLIT” structure). Measurements were carried out at HIT with protons (86.72 MeV, 150.95 MeV), carbon ions (100.07 MeV/u and 200.28 MeV/u) and oxygen ion beams (233 MeV/u). MMD and TimePix were applied for the beam intensity and overall beam profile monitoring. For spatially fractioned techniques the peak-to-valley dose ratio (PVDR) is an essential value that defines the efficiency of the MBRT. Both detector types provided PVDR results in excellent agreement with the radiochromic films data.

MMD and TimePix have shown a reliable performance for online beam profile monitoring. Calibrated detector could be used for dose monitoring in real time. The results of our studies suggest the possibility of MMD application in clinical practice. Their implementation will improve beam delivery to tumor tissue, fast imaging and evaluation of data, optimization of treatment regimes.

SP058.3 - Dose response evaluation of lung equivalent gel dosimeters by use of a new fitting algorithm

Author(s): Farideh Pak1, Hassan Ali Nedaie2, Abbas Takavar1, Hamid Salighedarad3, Vahid Vaezzadeh5

1Medical Physics And Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN, 2Radiotherapy Oncology Department, Cancer Research Centre, Cancer Institute, Tehran University of Medical Sciences, Tehran/IRAN, 3Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran/IRAN, 4Radiotherapy Oncology Department, Cancer Research Centre, Cancer Institute,Tehran University of Medical Sciences, Tehran/IRAN

Low signal to noise ratio (SNR) images of lung equivalent gel dosimeters compare to unit density gels, necessitate use of a different fitting method for data analysis. In this study a new fitting method (SQEXP) based on noise correction was introduced and its’ feasibility for quantifying absorbed dose in lung equivalent gels was investigated. The effect of new method was studied in term of dose sensitivity, linearity and correlation of calibration curve for both unit and low density gel dosimetry. The results were compared to conventional (Truncation) and a newly introduced method (VAREC).

Dose response of low density gel dosimeter showed wider detectable dose range (up to 20 Gy) against unit density gel dosimeter (10 Gy). It seems that reaction of excess amount of anti oxidant with hidden oxygen inside of styrofoam beads is responsible for this difference between low and unit density gel dosimeters. Relatively more sensitive calibration curve was obtained by SQEXP method in bothtype of gel dosimeters. Effect of signal denoising was more significant in low density gel dosimeters when high doses ≥10 Gy were absorbed by the gel. Detectable dynamic dose range of low density did not change by different fitting algorithms but in unit density gel dosimeters it was reduced by VAREC method. Dose sensitivity of low and unit dosimeters was reduced by use of VAREC method.

The SQEXP method seems to be more effective method than conventional algorithms for analysis of low density gel dosimeters especially where steep dose gradients exist such as in intensity-modulated radiation therapy (IMRT) and stereotactic radiosurgery (SRS).
Visible photoluminescence (PL) of pure LiF crystals irradiated with clinical proton and carbon ion beams has been investigated. The PL response was defined as the PL peak intensity measured at 670 nm when the irradiated pure LiF crystals were excited using the 458 nm line from an Argon laser operated in continuous mode at 25 mW. The emission band centered at 678 nm is due to the formation of F2 colour centres, stable at room temperature. Sets of three commercially available LiF crystals (5x5x0.5 mm³) were simultaneously irradiated. A custom-designed PMMA holder, diameter 30 mm, containing the LiF crystals, was positioned at 2 cm depth (dose plateau) in a PTW horizontal type water tank. The PL vs. dose (ab sorbed dose to water) was assessed for the intermediate energies of 148 MeV and 278 MeV/u for the proton and carbon ion irradiations, respectively. All irradiations were performed using a scanning beam system (AAA, Varian, Palo Alto, CA). The emission band centered at 678 nm is due to the formation of F2 colour centres, stable at room temperature. Sets of three commercially available LiF crystals (5x5x0.5 mm³) were simultaneously irradiated. A custom-designed PMMA holder, diameter 30 mm, containing the LiF crystals, was positioned at 2 cm depth (dose plateau) in a PTW horizontal type water tank. The PL vs. dose (absorbed dose to water) was assessed for the intermediate energies of 148 MeV and 278 MeV/u for the proton and carbon ion irradiations, respectively. All irradiations were performed using a scanning beam covering a 6x6 cm² field size. The PL vs. dose in the 2-20 Gy range exhibited a fairly linear behavior for both the proton and carbon ions irradiations, as shown in figure 1. In an independent set of irradiations, a test dose of 5 Gy was given to six sets of three LiF crystals at 62, 148 and 197 MeV for protons and 115, 278 and 380 MeV/u for carbon ions, in order to evaluate the PL signal dependence with beam energy. The response to the 5 Gy test dose for protons was within 3%, while the carbon ions response decreased systematically with increasing beam energy. The PL intensity observed at 115 MeV/u was 30% higher than the one observed at 380 MeV/u. In order to test the dosimetric capabilities of the LiF-PL system, two spread out bragg peaks (SOBP) irradiations were performed at 15 cm depth using beams in the 129-163 MeV and 248-316 MeV/u range for protons and carbon ions, respectively. The proton SOBP dose evaluation was correctly predicted by applying the proton calibration derived at 148 MeV, while the SOBP dose for the carbon ions was overestimated by 7% when using the 278 MeV/u calibration. The PL of LiF can be used for the accurate dose evaluation of clinical proton beams, while a more comprehensive investigation is required to effectively apply the PL of pure LiF crystals to the dose evaluation of clinical carbon ions.
SP059 - Drug Delivery and Control Release

SP059.1 - Nanotechnology applied in drug delivery

Author(s): Gabriela Barbosa¹, Pedro Augusto F.D. Silva¹, Glécia V.D.S. Luz², Lourdes M. Brasil³

¹Unb At Gama, University of Brasilia, Gama/BRAZIL, ²Pos. Engenharia Biomedica, UNIVERSIDADE DE BRASILIA, Brasilia/BRAZIL, ³Fga, UnB, Brasilia/BRAZIL

Nanotechnology is a multidisciplinary field that deals with the study, manipulation or rearrangement of particles at the nanoscale, which is equivalent to a billionth of meter, the material at this scale shows unlike physical, chemical and biological proprieties. This area has impacted a lot in the development of new products in various sectors and has been widely studied for offering effective solutions to several problems, such as pollution, energy rationing and cure of various diseases. What makes the field so promising is that the elements behave differently at the nanoscale, when compared to the macroscale. In this article it will be described how this field can be applied in the biomedical field, especially in controlled drug delivery systems using nanoparticles, nanobots and organometallic compounds, for greater effectiveness in the treatment of diseases.

Nanoparticles (NPs) are nanosized particles (3-200 nm), devices or systems that can be made using a variety of materials including polymers, lipids, viruses, and even organometallic compounds. The uses of NP with drug delivery systems have made a remarkable difference in site-specific release of drugs, owing to their physical and chemical characteristics and biological attributes. Various researches in this exciting area have been conducted and several formulations were released in the market and are now routinely used in clinics. In this review will be found a few nanoparticles more used in the medical area, as Solid Lipids Nanoparticles (SLN), Magnetic Nanoparticles, for instance. Nanobots or nanorobots is based on the creation of tiny machines that can do the functions of today’s machines, but more exactly, to develop projects that bring benefits in medicine, industry, and others areas. An ideal nanotechnology-based drug delivery system is a pharmacy: a self-powered, computer-controlled medical nanorobot system capable of digitally precise transport, timing, and targeted delivery of pharmaceutical agents to specific cellular and intracellular destinations within the human body. Some advances with these devices will be described in the review. Organometallic compounds are usually described as components having at least one metal-carbon bond. They also are considered nanoparticles. In the following review, will be discussed the application of Graphene and Carbon Nanotubes in drug delivery systems. Although some researches were not evaluated in vivo, there is a high expectation on this field. It is necessary study more about the behavior of nanoparticles at the organism, as well as figure manners to use these devices so that they do not exhibit toxicity to the body.

SP059.2 - Controlled electrochemical dissolution of iron alginate for smart drug release in micro devices

Author(s): Ashleigh Anderson, James Davis

Computing And Engineering, University of Ulster, Newtownabbey/UNITED KINGDOM

Smart devices that can routinely monitor patient’s health with little or no involvement from clinical staff have slowly begun to emerge over recent years and have arisen from significant developments in sensing and communication technologies. In cases where a rapid

seen in Figure 1, where the relative dose error decreases as a function of dose delivered.

Conclusion: The establishment of an overall accuracy and precision of this system provides a framework for potential areas of application such as high dose SABR treatments.
response may be required, a much more effective substitute would be the development of a truly smart system that could autonomously act on the information received from the sensing component and, where appropriate, deliver a therapeutic agent in a controlled manner. This presentation details the result of an investigation into the development of electrochemically initiated transitions of redox gels. The hydrogel structure can be held together through chemical or physical bonds and it is within the resulting network that drugs can be entrapped.

The approach to delivery is highlighted in Figure 1 where there is an electronically controlled layer that separates the drug reservoir from the skin. The core methodology employed in this project will involve electrochemical control to influence the porosity of a redox hydrogel, typically sodium alginate.

A) Hollow microneedle Alginete release film
Porous conductive membrane
Drug reservoir

B) Release of drug
Transport of drug through film to needle pore

Figure 1. Microneedle patch with alginete release film. A) before release (-1.1V) and B) after release (+0.5V)

The use of the iron as the binding agent is of prime interest in the present context as, in contrast to the other metal ions, it can be electrochemically cycled (Fe^{3+}/Fe^{2+}). The formation of the film and its dissolution are both controllable through electrochemical means. The oxidation of the Fe^{2+} to Fe^{3+} in the presence of the alginate will activate the crosslinking process and enable site specific deposition at the electrode. While this is similar to the polypyrrole and polythiophene films, there is a crucial difference. The electrochemical reduction of the coordinated Fe^{3+} to Fe^{2+} will result not only in a simple swelling of the film but rather its dissolution. Ordinarily this would be expected to cause significant issues, especially for a film in contact with biofluids, but the alginate-iron system is inherently biocompatible (the alginate is readily hydrolysed under normal physiological conditions) and this may be a critical advantage in the future use of redox films.

SP059.3 - Next generation transdermal drug delivery – An electrochemical approach to pH manipulation for controlled release within smart patch technologies
Author(s): Ashleigh Anderson, James Davis
Computing And Engineering, University of Ulster, Newtownabbey/UNITED KINGDOM

The majority of conventional controlled release technologies tend to be based around encapsulant systems in which a polymeric binder or gel typically responds to changes in the local environment in which the delivery device has been placed. The contents are typically released when the particle, capsule, film or droplet is exposed to the appropriate physico-chemical trigger (typically a change in pH) with the time-release-dose delivery characteristics controlled through manipulation of the encapsulant formulation. In this communication, the adaptation of this core strategy for use in the next generation of transdermal microdevice or smart patch is explored. A key feature of the approach is the ability to electronically trigger the release of the drug on demand.

The strategy relies on the electrochemical properties of a carbon composite film in which micro-nanoscale pores are created through controlled laser ablation. The porous carbon layer is then combined with the cellulose ester barrier film to complete the prototype patch as indicated in Figure 1. Under normal conditions the enteric coating remains intact with no diffusion of the drug to the bulk of the solution. Upon imposing a reducing potential on the carbon film top layer however, the local pH within the pores is dramatically increased such that hydrolysis of the ester occurs with dissolution of the protective barrier releasing the drug.

The presentation covers three aspects: the design of an innovative microprobe necessary for monitoring the changes in pH within the pores, the structural and electrochemical characterisation of the carbon film and the proof of concept demonstration of a model drug release.

SP059.4 - Protein nanocages for stabilization of bio-inspired emulsions/gel systems and cutaneous drug delivery
Author(s): Sierin Lim, Sathyha Moorothy Bhaskar, Mridul Sarker
School Of Chemical And Biomedical Engineering, Nanyang Technological University, Singapore/SINGAPORE

Self-assembling protein nanocages forming hollow structures are explored as potential carriers in various nanotechnology applications. The fact that proteins are integral parts of a biological system makes them promising for use as carriers for drug delivery, cosmetics and food emulsifiers. E2 Protein from pyruvate dehydrogenase multienzyme complex of Geobacillus stearothermophilus have the capability to self-assemble into a hollow dodecahedral cage of a unique size about 25 nm. The nanocages are extremely thermosensitive and porus with 12 openings of 5nm each. These inimitable characteristics of E2 protein nanocage are suitable to encapsulate...
and carry foreign molecules inside its cavity. E2 protein nanocages are engineered genetically or chemically, to shuttle drugs into the skin cells such as melanocytes (Figure-1) and keratinocytes (Figure-2), protein conjugated to Alex fluor-green, nucleus stain-blue) for the treatment of pigmented disorders. The existence of both hydrophilic and hydrophobic patches on the surface of E2 protein nanocages molds it to be a surface active bionanoparticle. Our preliminary results show the deposition of E2 protein nanocages at liquid-liquid interface under TIRF microscope (Figure 3). Thus the E2 protein nanocages can also be used as a potential stabilizer of bio-inspired emulsion and gel system. This study can be very functional in designing emulsion-and gel-based pharmaceutical products for topical application, skin care products and food products.

SP059.5 - Image-Guided Predictions of Nanoparticle Transport in Solid Tumors
Author(s): Shawn Stapleton1, Michael Milosevic1, Christine Allen2, Ian F. Tannock3, David Jaffray4
1Radiation Medicine Program, University Health Network, Toronto/ON/CANADA, 2Leslie Dan Faculty Of Pharmacy, University of Toronto, Toronto/ON/CANADA, 3Medical Biophysics, University of Toronto, Toronto/ON/CANADA, 4Techna Institute, University Health Network, Toronto/ON/CANADA

Due to the ability to preferentially accumulate and deliver drug payloads to solid tumours, nanomedicine, including liposomes, has emerged as an exciting therapeutic strategy for cancer therapy. Unfortunately, negligible increases in patient survival following liposome therapy have been observed in the clinical setting. This is due in part to the heterogeneous intra-tumoural transport of cytotoxic drugs, caused by chaotic tumour microcirculation and elevated interstitial fluid pressure (IFP). Here we explored the relationship between tumour microcirculation, IFP, and the intra-tumoural accumulation of liposomes using a combination of quantitative imaging and mathematical modeling. The combination of quantitative imaging and mathematical modeling presents a novel framework to guide nanoparticle drug-delivery in the clinical setting. A biological mathematical transport model, termed the intra-tumoural transport model (ITTM), was developed and used in combination with non-invasive imaging methods to predict liposome transport in solid tumours. The ITTM was validated using in vivo measurements of accumulation of a computed tomography (CT) liposome contrast agent made in three different tumour models. The ITTM attributed inter-tumoural heterogeneity of liposome accumulation to variations in IFP; however, several limitations were noted, including limitations in the accuracy of intra-tumoural liposome accumulation predictions based solely on IFP. These limitations were mitigated by developing a novel imaging method, termed Volume Fraction Imaging (VFI), to accurately measure additional key transport parameters, including microvascular permeability, perfusion, plasma volume and interstitial volume. VFI is based on the sequential injection of a nanoparticle and freely diffusible CAs. Simulations demonstrated that the VFI method substantially improves the accuracy and precision of plasma and interstitial volume, blood flow, and capillary permeability compared to standard pharmacokinetic modeling. In vivo experiments demonstrated that VFI substantially improves quantification of healthy and malignant tissue treated with Sorafenib, radiation, and mild hyperthermia. Using VFI we established that tumour perfusion and plasma volume are also key mediators of the intra-tumoural heterogeneity in liposome accumulation in several tumour models. We probed the relationship between tumour microcirculation using VFI, IFP using a novel image-guided robotic needle positioning system, and the intra-tumoural distribution of liposomes using volumetric micro-CT imaging where performed. A strong relationship between the radial distribution of IFP, metrics of tumour perfusion, and the intra-tumoural accumulation of liposomes was observed. Therefore, both tumour perfusion and elevated IFP play an integral role in mediating the intra-tumoural accumulation of liposomes, and strengthen the need to account for intra-tumoural heterogeneity in transport properties for guiding the use of nanomedicine in the clinical setting. This work provides a pivotal piece of the image-guided drug delivery schema whereby quantitative imaging can derive patient specific information on drug pharmacokinetics, biodistribution, intra-tumoural transport, biological targets, and mechanisms of resistance. Integrating image-derived information with an established mathematical framework based on the ITTM can conceivably predict drug-transport and treatment response. This represents a major leap forward compared to the conventional chemotherapeutic strategies whereby optimal dosing and scheduling strategies can be prescribed and adapted on a based on validated mathematical models of drug delivery that are informed by quantitative imaging methods.

Optogenetics uses light to manipulate neural activity which has several advantages over conventional electrical stimulation approach including specific cell-type targeting with precise temporal precision, simultaneous stimulation using different wavelengths of light and relatively harmless to target tissue. In optogenetics experiments, targeted neurons are transfected with photo-sensitive proteins (opsins) for subsequent exciting or silencing neurons with pulses of visible light.

Optogenetic stimulation offers the prospect of treating lifetime conditions; however, current optogenetics available commercially are mainly connected with wires coming out of head of the animal head which brings a risk of infection and is vulnerable to damage from chewing or scratching. Also, current light stimulation systems are generally not suitable for chronic use due to the risk of infection associated with components located outside the brain. This study aims to investigate the technical feasibility of implementing a fully implantable optogenetics system supporting long-term light stimulation as well as for feasibility of wireless transmission of recorded signals outwards.

A miniature LED die with dimensions of 280μm by 280μm has been sourced with an output wavelength of 470nm which is suitable for exciting the opsin ChR2. The power needed is about 6.4mW to deliver the required optical power for opsin excitation. This is an exciting proof-of-principle outcome showing adequate light from a small package of components consuming a manageable amount of electrical power.

In the experimental setup, the LED die coupled to a 200μm optical fibre is feasible and sufficient to activate ChR2 (~32μW). With 80% of the light transmitted with a bend radius of 2mm, the fibre can be tracked from the brain to the wirelessly powered telemeter located in the abdomen to form a fully implanted optogenetics system. Our results show that LED-fibre optic system is able to generate a cellular response in a ChR2-expressed cell with a short pulse (4ms) of light. The cellular response generated can also be sustained by long duration light stimulation (500ms). The amplitudes of the cellular response can be controlled by changing the light intensity emitted on the targeted cell. This can be achieved by modulating DC voltage supply using Pulse-Width Modulation (PWM) technique. This technique is favorable for implantable device because it is easy to implement using a microcontroller and does not increase the size of the circuit. This experiment motivates the use of the custom-made LED-fibre optic system in vivo chronic rodent studies in the future.

Critical questions for technical feasibility include size, optical power, heat generated and physical delivery of the light to the region requiring illumination have been considered.

The proposed module has been validated to measure individual cellular response to optical stimulation photosensitive rat brain slices performed. This experiment motivates the use of the custom-made LED-fibre optic system for future in vivo chronic rat studies including animal behavior as well as wireless transmission of recorded brain potentials during various treatment schemes. The implantable wireless optogenetics would have great potential to enhance basic neuroscience research and help develop interventions for various neurological disorders, such as Parkinson’s disease.

**SP060.3 - A method to determine the variation of irradiance in bilirubin lamps as function of the time of use**

*Author(s):* Graciela M. Salum1, Di Teodoro Cota2, J Salerno3, E Marino4, R D. Piacentini5

De Cs Exactas, Ing Y Agrim/unrosario, Laboratorio de Eficiencia Energética, Sustentabilidad Cambio climático, Rosario/Argentina

Hyperbilirubinemia is a pathologic process consisting of the abnormal increase of the amount of bilirubin in the circulating blood, which can cause jaundice. A common treatment is expose the premature newborn to the phototherapy treatment, with lamps that emit in a specific region of the electromagnetic spectrum (mainly 410-550 nm). In the present work we describe one irradiance analysis method to this type of bilirubin lamps (in the case a Phillips TL20W/52), based on the determination of the intensity variation as a mathematical function depends on time (hours) with which we can simulate this behavior. We used the Exhaustive Approximation method combined with the Distinguish region-curve method for the determination of the corresponding function.

Also, we compare the spectral irradiance of the lamp, with the solar spectral irradiance measured with a high quality double monocrystal Optronic 756 spectroradiometer, the day October 26 of 2012, at 12:49 local hour, in Rosario, Argentina. As a consequence, it was observed that the lamp intensity is very small compared with the solar one, which means that a careful analysis of the solar radiation incident on a given place needs to be made, if a treatment with natural radiation would be used for bilirubin reduction.

**SP060.4 - Study of the sensibility of induced heat effects in edible oil measured by interferometric techniques**

*Author(s):* Joel Espinosa-Barrios1, Francisco Corella-Jimenez2, Alejandra Guillen-Peralta2, Amy Avila1, Gerardo S. Romo-Cardenas2, Andres Piña-Barrera3  
1School Of Engineering, Montemorelos University, Montemorelos/Mexico, 2School Of Health Sciences, Montemorelos University, Montemorelos/Mexico

Currently the use of edible fats and oils in the preparation of fried products has increased, it is known that excessive consumption of foods containing fats, can have a deleterious effect on the health of people, forcing increasingly strict control of oils and fats in fried foods to maintain quality of fried foods and ensure their safety, lack of laboratory facilities in fried food preparation establishments, limit the compliance of existing quality standards requiring new simple alternative methods to be used by the user.[1] Optical interferometers are instruments that can make very precise measurements of objects using the pattern of interference of two waves of light. These devices have been used to characterize materials and study their properties. This paper propose a new prototype of this application in order to reach a characterization protocol of fluids with low differentiation of components. Results in oil samples indicate that it is possible to make characterization using interferometric techniques.
SP060.5 - Design and study of Infrared-Guard
Author(s): Shanmugam Senthilkumar
Dept. Of Radiotherapy, Govt. Rajaji Hospital & Madurai Medical College, Madurai/INDIA

Introduction: Gantry - couch collision is a serious concern for cancer patient treatment planning of the radiotherapy machine. The radiotherapy machines moving parts may cause collision between the treatment couch and the treatment head, which affects the accuracy of the machine and sometimes a replacement of parts. If a patient interferes, it results in severe injuries. In this work we have developed Infrared Guard (IRG) to prevent gantry - couch collision in the Radiation Therapy machine.

Material and Methods: The Infrared Guard consists of a distance measuring sensor unit, composed of an integrated combination of PSD (position sensitive detector), infrared sensor and signal processing circuit. The infrared sensor is made up of the emitter (infrared LED) and detector (photodiode). The emitter emits IR light pulse and the receiver detects the corresponding light pulse. The infrared intensity of the emitter influences the detection range. On the IR receiver side, the desired output voltage depends on the detection distance. This output voltage signal connected to an analog amplifier, comparator, or Schmitt-Trigger, to control various functions. IRG device placed in the treatment machine gantry, which is inner side of the gantry and above to the gantry angle indicator. IRG device monitors the region between the collimator face and the treatment table (or) patient. The IRG provides an infrared invisible sensing shield, which covers the entire collimator face. The IRG device sensing area or protection zone distance can be varied according to the requirement with adequate clearance. If the potential collision is detected by the IRG device in the protection zone, the radiotherapy machine will stop the movement and the red LED will glow and also buzzer will produce sound. We have also provided the IRG OFF key in the machine. If you want to override or turn off to the power to the IRG device a blue light will glow and illuminating words Infrared Guard OFF will appear.

Results and Discussion: We have studied this IRG device to monitor the accuracy in the radiotherapy machine using phantoms and patients. Our method correctly confirmed clearance between the patient/treatment table and the gantry. This device is easy to handle, inexpensive and stops the machine movement when the gantry and the couch come nearer to each other. Infrared Guard provides an additional level of safety to automated radiotherapy machine operation. IRG monitors the closeness of the patient treatment couch to the treatment head during remote movements and restrain or stops machine movements prior to a potential collision. IRG provides an additional “set of eye” to monitor and minimize risk. IRG does not require physical contact to detect potential collision. IRG anti-collision device improves the performance of the machine and most importantly reduces the chance of collision.

SP061 - Improvement of Diagnosis and Therapies

SP061.1 - Development of heart sparing device for Left Breast Radiotherapy with deep breath-holding
Author(s): Shanmugam Senthilkumar
Dept. Of Radiotherapy, Govt. Rajaji Hospital & Madurai Medical College, Madurai/INDIA

Introduction
Breast radiotherapy is now part of the routine care of patients with early breast cancer. Adjuvant radiotherapy for post-mastectomy breast cancer patients consists of a pair of tangential photon beams treating the breast tumor bed. In addition, internal mammary chain (IMC) and supraclavicular (SCV) beams are also employed to treat the corresponding lymphatic nodes within the region. Radiotherapy has been shown to reduce recurrence and improve the survival rate for post-mastectomy breast cancer patients. However, the benefits of adjuvant radiotherapy is compromised by the secondary cardiac mortality that occurs 15 to 20 years after the therapy has completed. Therefore, it is critical to develop radiation techniques that retain the benefits but reduce late toxicity to the heart and other organs at risk. Patients with left-sided breast cancer who receive chest wall radiation have increased risk of treatment related cardiovascular morbidity. To reduce the dose to the heart, it has been suggested that electrons be used in the IMC beam. Another strategy to reduce cardiac dose is to employ breathing adapted radiotherapy, including the deep inspiration breath-hold (DIBH) technique. It has been demonstrated that employing the DIBH technique in tangential beams appreciably reduces cardiac dose. However, there has been no study on the effect of utilizing the DIBH technique in IMC electron beams. The aim of this study was to evaluate the effect of decreasing the irradiated cardiac volume in breast-conserving treatments (BCT) with indigenously developed deep inspiration breath-hold device (DIBHD) using breath-adapted radiation therapy (BART).

Materials and Methods
We have developed indigenously deep inspiration breath-hold device (DIBHD), which consist of laser sensor, in-house software, video goggles, a breath hold signal device, alarm and visual indicator. The sensor is used to display the breath-hold position of the chest wall in the computer monitor as graphical signal as well as digital. Patients can able to see their breath hold position while using the video goggles and maintain the uniform level without reducing the lung volume. Once the threshold level reduces, patient starts to exhale the radiation will be stopped, simultaneously alarm will produce sound and visual indicator glows.

Results
DIBHD has been used for the left sided breast cancer patients during the radiotherapy in deep inspiration breath-hold. The tangential fields were planned for each respiratory-gated CT image. The dose-volume histograms (DVHs) of the heart, lung, and breast of each respiratory phase were compared. Patient’s position during each breath hold was carefully monitored and make sure the heart is positioned away from the chest wall. Radiation was delivered during these repeated breath holds. A deep breath pulls the diaphragm and heart down and out of the radiation beam path. Delivering radiation treatment during these deep breath holds protects the heart from radiation. We concluded that radiotherapy using DIBHD facilitates a reduction of the irradiated heart volume which enables more complete cardiac sparing without any compromise of PTV coverage.
Health Technology Assessment (HTA), although having been routinely applied in drugs and surgery for a long time, is still quite challenging in medical devices. The reason is that the main objective of HTA studies for devices is not optimization of the cost-effectiveness ratio, but rather decisions about procurement and/or incorporation of the apparatus. The clinical benefit is not expressed in terms of quality of life, but in the rate of diagnostic yield, comfort of the clinician, or the extent to which the technology makes the therapy shorter and/or more patient-friendly. Utilization of multiple-criteria decision-making methods for evaluation of the aggregated clinical, technical and user’s effect (outcome) is recommended as the input to cost-effectiveness analyses. Different methods are derived for strategic and/or operational assessment of new technology.

Bacterial contamination of chronic wounds has long been a major concern for those involved in the management of diabetic foot disease (DFD). The latter is an increasingly common complication of diabetes whose treatment has a profound impact on both patient and healthcare resources. In 2013, global healthcare expenditure for diabetes totalled $548 billion. With the ever increasing population of people with diabetes expected to increase by 55% in 2035, we can expect expenditure to reach $627 billion and upwards. A study has estimated that a population with diabetes costs three to four times greater than a population without. The majority of these costs are due to the complications that arise from diabetes such as neuropathy, infection and ulceration. It has been estimated that approximately 25% of all diabetes related hospital admissions in the US and the UK are due to such complications and consequent limb threatening infections. Approximately 15% of patients with diabetes will suffer from foot problems and around 7% have a foot ulcer at any given time. Around 56% of foot ulcers become infected, making patients 30 times more likely to have an amputation compared to the general population making it the most common cause of lower limb amputation.

While there has been considerable activity in the development of wound dressings that aim to minimise bacterial contamination and aid the healing process, the majority are passive and possess little or no diagnostic capability. The present communication details the results of an investigation into the use of a smart bandage which can permit electrochemical interrogation of the wound environment and therein provide the possibility of more timely and effective interventions in the management of the wound.

Carbon loaded polyethylene films were selected as the base substrate for a mechanically flexible and conductive sensing material for use in wound monitoring technologies. The films were processed using laser ablation of the surface to increase the effective surface area of the electrode and were then subject to an oxidative electrochemical etch to improve the electron transfer kinetics. The surface morphology of the resulting film was analyzed and the electrode performance in relation to monitoring uric acid, a key wound biomarker, was optimized. A prototype smart bandage interfaced with a miniaturized potentiostat capable of monitoring the wound condition was developed and the response to urate harnessed to measure both the wound pH and wound severity. The viability of using urate for use in complex fluids was assessed using whole blood and other potential interferences. The mechanical flexibility of the polyethylene film is ideal for incorporation within existing dressing materials and could be produced in bulk at relatively low cost, a pre-requisite given the frequency with which dressings need to be replaced.

We have developed a system that can produce 3-dimensional single photon emission computed tomography (SPECT) images from a handheld camera that can be moved freely by a surgeon around a patient. This system is called FreeSPECT, will better localize lymph nodes for sentinel lymph node biopsies (SNLB). With 3-dimensional image-guidance that can be linked to high-resolution anatomical images from CT or MR, surgeons will be able to more accurately remove lymph nodes and plan around sensitive tissues. The FreeSPECT system we have developed is based upon a SPECT system from NDI, which is small in size and MR compatible. Figure 1 shows the system including the electronics cabinet, gamma detector, and user interface. The silicon photomultiplier (SiPM) detector head has 16 pixels in a square 4x4 pattern, with a 5 mm thick CsI(Tl) scintillator. The detector efficiency is 149.7cps/MBq at 50 mm source distance, and signal multiplexing allows sampling of each pixel every 4 μs. In-house developed navigation platform “GTxEyes” provide gamma image acquisition, real-time tracking, navigation, visualization, and reality augmentation. This platform is developed based on open-source toolkits and libraries including VTK, ITK, IGSTK, and OpenCV, as well as our own proprietary image reconstruction and co-registration algorithms. Additional capabilities of this platform include critical organ monitoring with visual/audio alerts and image overlay of multi-modality images. Fast deformable Demon image registration algorithm is also available to register pre-operative images (and/or contours) to intra-operative images such as the proposed Free-Hand SPECT image. The prototype FreeSPECT system has integrated optical tracking technology (Spectra, Polaris, NDI), a reference tool affixed to the camera’s body for identifying the position and orientation of the gamma camera images in 3D. To precisely locate the gamma camera images in space, the spatial relationship between the tracking tool and camera space is first calibrated. In the localization process, the clinician uses the handheld gamma camera to scan above and around the region of interest. The software records the 6D position and orientation of the camera simultaneously with the gamma image acquisition at every instant. In the prototype system, this recorded information is saved in ASCII text format for subsequent tomographic image reconstruction. The SPECT image reconstruction is based on the ordered subset expectation maximization algorithm as implemented in the NiftyRec open source tomography toolbox. Preliminary results from the FreeSPECT prototype system are shown in Figure 2.

Alterations in the biomechanical properties of cells are important in many pathologies including cancer, neurodegenerative diseases, and autoimmune disorders. For example, the more aggressive molecular subtypes of breast cancer may express different biomechanical phenotypes due to subtype-specific mutations which code for proteins that regulate the cytoskeleton. Microtubule destabilization and other cytoskeletal dysfunctions play a pivotal role in neuropegenerative disorders such as Alzheimer’s disease. In autoimmune diseases, cytoskeletal changes in T cells are key to signaling, immune recognition, and activation. Our research at Utah Valley University is currently exploring the capabilities of high-frequency ultrasound for detecting variations in the biomechanical properties of cells. To date, high-frequency (10-100 MHz) ultrasonic spectra have been found to be sensitive to breast cancer cell types and chemical modification of the cytoskeleton in cell cultures. The cells are non-invasively probed using a pulse-echo measurement. Time-domain signals acquired from cells are converted into frequency spectra and analyzed for spectral features that correlate to biomechanical properties. Ultrasonic scattering models, experimental data, and data analysis methods such as principal component analysis have confirmed that high-frequency ultrasound can detect changes in the cytoskeleton. However, a critical problem with the current approach is the strong ultrasonic reflection from the well bottom of the cell culture plate, which interferes with the weak ultrasonic signals from the cells adhering to the bottom. The objectives of this study were to develop an approach to eliminate the well-bottom interference from the cell signals, and to provide a capability for probing cells in liquid suspension (thereby expanding application to cells extracted from tissue and blood). The approach uses acoustic levitation to induce free-floating cells into forming a thin, suspended, planar layer which can then be probed by high-frequency ultrasound. Acoustic levitation is accomplished by establishing an acoustic standing wave in the media using a low-frequency ultrasonic transducer. A significant challenge in the acoustic levitation of cells is the random motion of the cells about the node position of the standing wave. This paper reports on a new method for damping cell motion during acoustic levitation. The method uses harmonic modulation of the standing wave to create nodal regions of greater stability and cell localization as compared to a single-frequency standing wave. Numerical simulations indicate that such “acoustic wells” can be created using a multifrequency layered piezoelectric transducer to modulate the standing wave with an optimized set of harmonic frequencies. Breast cancer cells having distinct spectral signatures will be tested to validate the approach. The acoustic levitation system will consist of a 30-MHz function generator, an RF amplifier, and a multifrequency (0.1-1.0 MHz) layered piezoelectric transducer. The high-frequency ultrasound system will consist of a 50-MHz immersion transducer, a high-frequency square-wave pulse/receiver, and a 1-GHz digital storage oscilloscope. Our research group has developed a new method for stabilizing cell motion during acoustic levitation using numerical simulations. This new method promises to not only expand the capabilities of high-frequency ultrasonic testing of the biomechanical properties of cells, but also has applications as a 3D patterning approach in tissue engineering.
SP062 - Clinical Process Analysis, Optimization, Productivity and Benchmarking

SP062.1 - Guaranteeing the quality of rigid endoscopes with the ScopeControl
Author(s): Herke Jan Noordmans1, Rens Wientjes2
1Fb Medical Technology And Clinical Physics, UMC Utrecht, Utrecht/NETHERLANDS, 2Fb Medical Technology And Clinical Physicist, UMC Utrecht, Utrecht/NETHERLANDS

As rigid endoscopes are re-used after minimal invasive surgery, they degrade over time. To guarantee the optical quality of a rigid endoscope for the next surgery, the ScopeControl has been developed to measure key optical parameters such as light transmission, color correctness, focus, fiber transmission, viewing angle and field of view. The ScopeControl is placed in the reprocessing cycle right after cleaning, before wrapping and sterilizing the endoscope. After a measurement has been performed, all parameter buttons/indicators should turn green. When, however, a parameter button/indicator turns red, its value falls below a pre-defined threshold (acceptation criterion) and the endoscope should be rejected for further processing.

In 2013 a pre-commercial version of the ScopeControl has been tested in six hospitals in the Netherlands. It proves to be stable, and able to measure optical parameters with sufficient precision that it can discriminate between good and bad endoscopes [1]. Since April 2014, the commercial version of the ScopeControl has been in use at the sterilization department of the UMC Utrecht (about 4000 minimally invasive surgeries a year). In this project we want to address several issues when introducing the ScopeControl in the clinical process:

1. What kind of training people of the sterilization department should get in handling and interpreting the results of the ScopeControl.
2. What kind of tracking is needed for endoscopes. Conventional basket tracking systems are often not sufficient as endoscopes are easily swapped between baskets. The ultimate goal is to track on endoscope level (e.g. using a data matrix or RFID).
3. What should be agreed between the departments of sterilization, OR and medical technology about rejecting/accepting endoscopes when reprocessing them or sending them in for repair or replacement. What can be said about the rejection/acceptation levels? Generally a repaired or new endoscope should have a higher quality than an endoscope that is still good enough for surgery. There should be some bandwidth where endoscopes may deteriorate slowly.
4. What kind of reports can be derived from such a system and how can these results be coupled to information from other electronic registration systems in the hospital like basket tracking and OR management systems.
5. Which steps in the reprocessing cycle may damage endoscopes and can we get an idea of their impact? Think of handling, transport, cleaning, disinfection and sterilization.

These issues are illustrated in two examples: The replacement of a large number of rigid endoscopes in a public tendering, and the large fall-out of large number of cystoscopes for children. We look forward to a live discussion to see whether these problems are recognized in other hospitals and which approaches other people have found to address these problems.

SP062.2 - Low-entry level CT exam times and availability in worldwide markets
Author(s): Renan M. Almeida1, Fernando C. Coelli2, Andrei L. Pires3, Renan M. Almeida4, Wagner C. Pereira5
1CEFET “CSF” RJ, Itaguai/BRAZIL, 2Cefet “CSF” RJ, Itaguai/BRAZIL, 3UFRJ, Rio de Janeiro/BRAZIL, 4Peb/coppe, UFRJ, Rio de Janeiro/BRAZIL

Context and background: Computerized Tomography (CT) is widely used for disease diagnosis, treatment planning, and follow-up. Currently, its state-of-the-art is a 320-slice equipment, but machines with one, two, four and 16 slices are still used in many countries. Exam speed (and, thus, number of exams per period of time) may change among models, but the smallest slice thickness is usually about 1mm regardless of the number of detector rows. However, most of the basic models already had their production discontinued, a situation that makes CT entry level more expensive, and, therefore, decreases its adoption in less developed countries.

Objective: To study the differences in productivity (exams/unit of time under real working conditions) between 1, 2, 4 and 16 slices CTs.

Methods: Four CTs (with one, two, four and 16-slices) were studied relatively to their performance in patient exam time, divided as: i) patient arrival; ii) patient initial preparation; iii) patient positioning in the equipment; iv) data scan; v) examination time and vi) time for patient departure. Times were measured in minutes and seconds by two researchers with an Android Tablet and a timer application. Equipment were located in Rio de Janeiro city or nearby cities in Brazil, 2013-2014. Additionally, an Internet search was performed among equipment producers trying to identify the supplier of the simpler models in the Asian, European and USA markets.

Results: A total of 85 exams were followed, and three had to be discarded, one due to equipment failure at the moment of the exam and two due to patient arrival delays. Average times for the arrival / preparation / positioning / scanning / departure stages did not differ markedly. As for the “scan” stage, the average time for the single slice case was 8‘38”, as opposed to respectively 2‘05”/ 2‘31”/ 2‘41” for the remaining models.

Concerning model availability, the Internet search identified that few older model options are still available, with the number of slices beginning at “sixteen” among USA and European manufacturers.

Conclusion: Despite their wide variations in technology, average time differences among the studied models were small for the “non-examination” stages, indicating that the general (including ergonomic) characteristics of the equipments did not change markedly. Regarding the “scan” stage, however, 2-16 slices models had a similar and clearly better performance relatively to the single-slice model, and, thus, a similar productivity could be achieved with the former models. This is an important consideration, given that productivity is important both for the public health sector (allowing for attending a larger patient population) and for the private sector. Therefore, these models, if still available, could satisfy the demand of many less developed countries, but the Internet search identified that entry level now refers to 16 slices and over. An alternative for keeping low cost models in production would be the development of “upgradeable platforms” by manufacturers, allowing for the acquisition of more simple alternatives that could be adequately upgraded along time.
SP062.3 - The critical evaluation of AV control features in modern pacemakers and cardioverters

Author(s): Kazimierz Pieczalski, Tadeusz Palko

Warsaw University of Technology, Warsaw/Poland

The modern prostheses of different vital systems of human body are equipped in many control features related to the physiological behavior of replaced systems. The critical evaluation of some algorithms for the synchronization of the heart conductive systems that are implemented in modern pacemakers and cardioverters is goal of our evaluation. We describe our clinical evidence that the algorithms should be customized to individual patients. Two of the most important pacing parameters: default atrioventricular interval (AVI) and AVI adapted to heart rate (HR) were evaluated by the authors. The criterion for enrolment to the both study groups was the 80% pacing recorded by the pacemaker holter systems and 100% pacing during the duration of the test.

The goal of the studies was to assess the differences between SV for optimal AVI and SVs for default AVI values proposed by two of the biggest word pacemaker companies and the impact of varying HR on the optimal AVI in two groups of 20 paced patients: first (mean age 74.0 years +/- 7.0 years) consists of 4 females (mean age 75.3 +/- 6.1) and 16 males (mean age 74.3 +/- 4.1) and second treated by DDR were enrolled into the study.

The mean value of SV for optimal AVI achieved in the first clinical study is pretty close to SV for default AVI' (150 ms) and differ from SV for the second default AVI“ (170 ms). Significant changes (p<0.05) were found for SV vs SV“. The high SD level of optimal AVI‘s (mean 148.50 msec., SD 41.07 msec.) shows wide range of its variations assessed for some patients. The estimated default AVI” may be based on a different population of patients for instant North American. All of the facts listed above prove the assumption that the default AVI values preset by companies can lead for nonoptimal settings for some patients. Such wrong settings can be especially important in group of patients with poor condition of cardiac muscle which limits the physiological adaptation of the heart to an intense exercise. The results of the second study of reaction of AVI to increase or decrease of HR lead to similar conclusion. The normal relationships between shorter AVI for faster HR and longer AVI for slower HR simply do not work for some, pretty significant in presented study, number of paced patients with impaired systole by atrophy of heart muscles geometry and non physiological systole of paced ventricles (the impulse is propagated from the apex of the heart in opposition to physiological direction of impulse propagation).

Conclusion: The presence of non physiological behavior of the heart conductive system should be taken under consideration during adjustment of parameters of pacing treatment.

SP062.4 - Assisted Reproductive Technology Center Design with Quality Function Deployment Approach

Author(s): Alessio Lusch, Massimiliano Monti, Ernesto Iadanza

1Information Engineering, University of Florence, Firenze/Italy, 2ESTAV Centro, Firenze/Italy, 3Department of Information Engineering, University of Florence, Florence/Italy

Assisted Reproductive Technology (ART) is the technology used to achieve pregnancy in procedures such as fertility medication, artificial insemination, in-vitro fertilization and surrogacy. The paper shows an application of Quality Function Deployment method to Careggi Hospital ART Laboratory of Florence in order to give a prioritization order for ameliorative interventions.

SP062.5 - Study of the Sensitivity on the Measurement of the Prevalence of Total Cholesterol in Blood Serum by Interferometric Techniques

Author(s): Betty Hernandez-Zacarías, Gerardo S. Romo-Cardenas, Alejandra Guillen-Peralta, Alex Muñoz-Arpaiz, Juan Alvarez-Arana, Ismael Chable

1School Of Engineering, Montemorelos University, Montemorelos/Mexico, 2School Of Health Sciences, Montemorelos University, Montemorelos/Mexico

Current blood testing techniques require the use of sensitive equipment and a constant consumption of specific chemical compounds in order to analyze fluid composition and concentration. It is known that optical interferometers are instruments that can make precise measurements of objects using the interference pattern of two light waves. These devices have been used to characterize materials and to study their properties. Interferometric studies results, prove that by this type of optical arrangements combined with image processing, enables a method that applies for fluid characterization. Being this a non-destructive protocol that could be used for different applications in engineering. This study, propose the use of optical interferometry to analyze blood serum in order to explore the possibility of developing an alternative method for blood sample analysis. The methodology consists of analyzing different blood serum samples previously quantized to determine the effect of the variability of its components in the acquired interferograms. The results show an unexpected behavior of the acquired interferograms in relation of the amount of total cholesterol included in the samples, this in relation with the information generally considered from the medical practice.

The scope of this paper seeks to apply technology and optical engineering also consider the effect of the prevalence of lipid components in blood serum in order to develop a standardized technique that allows the study of concentration information from acquired interferograms and thus validate the option as an alternative to the quantization of such compounds. Helping to complement the knowledge of the biochemistry of the blood and develop novel methods for quantization and analysis of its components by non-destructive techniques and less expensive methods known on the market.

SP062.6 - Critical role of sustaining technology and utilities in healthcare institutions facing disaster through development of an international center for information and training of health technology managers on disaster preparedness

Author(s): Yadin B. David, Caridad Borrás, Fred Hosea, Douglas Drepps

1Biomedical Engineering Consultants, LLC, Houston/United States of America, 2IUPESM, Washington DC/United States of America, 3Clinical Technology, Kaiser Permanente, San Francisco/CA/United States of America, 4Clinical Engineering, Mercy System, St. Louis/O/United States of America

Study/Objective

Promote awareness of critical role of sustaining technology and utilities in healthcare institutions facing disaster by exploring development and establishment of international center for information and training of health technology managers on disaster preparedness and situation-awareness methodologies.

Background

Review of disasters that affected healthcare institutions suggests a need to make technological systems more robust and better trained users about disaster preparedness. The burden is magnified due to ever growing critical dependency on technology, i.e. central oxygen, vacuum, nuclear, radiological equipment, communication systems.

Methods

The need for a training center based on a case study of the impact
on several hospitals: a flood from tropical storm affected several hospitals and their technological systems in Houston, Texas, 2001. The problems caused by rising water, the immediate response, the recovery efforts and the financial losses will be analyzed. This will also include the transfer of learned lessons to environment of resource-poor countries.

Results
Water caused shutdown of electrical, air, vacuum systems and submerged areas containing radiological equipment. Patients had to be evacuated, unfortunately four patients died, research animals, and years of investigation data lost. The case shows lack of technology-focused plans for triaging healthcare systems and of training programs. There was lack of understanding of systems (including networks) and devices’ vulnerability, especially when multiple systems crushed. The possibility of unique hazards like those from radiation-emitting devices and radioactive materials, other biomedical equipment such as mechanical ventilators were considered last. Prioritization of backup and strengthening resilience of technology prior to disaster and during disaster were a last minute approach. The recovery focused on commissioning technologies critical to life. Had the facility been better prepared, lives and financial losses would have been minimized.

Conclusion
Disaster preparedness plans in healthcare institutions must include knowledge of the vulnerabilities they may face and plans to mitigate risk of operations disruption due to technology and utility issues.

SP063.1 - The Current State of Clinical Engineering Education and Career

Author(s): Yadim David
Health Technology Management, Biomedical Engineering Consultants, LLC, Houston/UNITED STATES OF AMERICA

Today’s practice of healthcare has grown to depend on the deployment and integration of technological tools for the delivery of its services like never before. Furthermore, these technological tools are being integrated into systems requiring competencies and expertise that challenges conventional training. It is critical, for the practice of safe and effective healthcare services, that these systems and their integrated technological tools are well planned, managed and safely serviced throughout their complete life cycle. Not only the dependence on these systems has grown but even more so, the quality and the volume of the intelligence embedded within these technological tools. Intelligence that guides the management of patients’ conditions. As example, the emergence of the utilization of electronic medical records, of health informatics, surgical robots, 3-D medical imaging, smart infusion pumps, bedside telecommunications, wireless accessibility and mobile devices. It is clear, therefore, that clinical engineers for successfully managing their hospital’s clinical technology program require new knowledge and additional competencies.

In reviewing the academic preparation of engineers for career in the clinical environment, the clinical engineers, it seems obvious that most if not all are based in the biomedical engineering academic programs. While there are some joint sciences, the training of clinical engineer is different from training of biomedical engineer. The curriculum and the format of the clinical engineering programs must anticipate and train for the specific body-of-knowledge needed for practicing as clinical engineering professional. Therefore, helping its graduate to become successful practitioners that will pursue, after graduation, further professional development and certification supported by lifelong clinically related continuing education.

This presentation will provide a review of the healthcare technological tools and their integration into systems. It will further identify how these changes influence the body-of-knowledge that clinical engineers must have. It will summarize some suggestions on how to improve clinical engineering education programs so that their graduates will be successful in their career, happy as professional practitioners, and contributors to best possible care outcomes.

Objectives
1. To describe the relationship between changing healthcare and clinical engineers practice
2. To identify why changes in practice of clinical engineers impact their education and preparation
3. To link specific knowledge that must be part of future clinical engineering education and their career
The purpose of this presentation is to report on the progress towards Medical Physics becoming a regulated health profession in Alberta.

Medical Physicists in Canada have a nationally recognized certification system through membership with the Canadian College of Physicists in Medicine (CCPM). While most Medical Physicist employers desire this membership or its equivalent, it is enforced only voluntarily by hiring institutions and managers. There is no legal requirement for membership with the CCPM to work as a Medical Physicist. Many of the clinical activities performed by Medical Physicists that can have direct clinical consequences for patients in terms of detecting and treating disease can be legally performed by anyone. This lies in contrast with many of our professional peers (physicians, radiation therapists, nurses, etc.), where provincial colleges independently define a scope of clinical practice, regulate those who may conduct that practice, and restrict the practice of certain activities to those registered with the college.

By defining a scope of practice and requiring members of a profession to meet and maintain minimum standards of competence, professional regulation ensures both patient safety and a minimum standard of care. Root cause analysis commonly identifies lack of Medical Physicist involvement, training, or qualifications as a significant contributor to major radiation therapy accidents and near misses. This suggests a key link between quality and safety and the regulation of Medical Physics.

In Alberta there are approximately 40 qualified medical physicists. For over five years the Association of Medical Physicists in Alberta (AMPA) has pursued professional regulation under Alberta’s Health Professions Act. In 2011, AMPA submitted an application for professional regulation to the Government of Alberta. Government feedback identified small physicist numbers as a primary barrier to regulation: the administrative workload of operating a professional college, and the cost of potential investigations and disciplinary committee hearings (involving legal council) were deemed prohibitive. However, subsequent feedback suggested the potential viability of a joint application with the Alberta Association of Clinical Laboratory Doctoral Scientists (AACLDS), an organization also seeking regulation, but limited by similar membership numbers. AACLDS represents professions including clinical chemists, microbiologists, geneticists, and toxicologists who share several professional similarities with medical physicists. Its members complete PhDs, then do two years of clinical training before writing a national certification exam. In the newly proposed model, Medical Physicists and the professions represented by AACLDS would join and be administrated by the College of Physicians and Surgeons of Alberta. The CPSA is a natural choice because (i) this college is the provincial accreditation body for ionizing radiation devices below energies of 1 MeV and (ii) our groups share common professional ground with physicians and surgeons, including a balance of clinical and academic responsibilities, and the extensive training involved in our professions.

At the time of this abstract submission, AMPA and AACLDS are in the process of submitting this joint application to the Government of Alberta. If successful, Alberta would become the first province in Canada designating Medical Physicists as a regulated health profession.

This talk will present an overview of the objectives of the International Medical Physics Certification Board (IMPCB), progress made since its formation, and the results of recent discussions to assure that the IOMP will play a major role in IMPCB governance in the future. The IMPCB was established in 2010 with the assistance of the Certification Task Group of the IOMP Professional Relations Committee, with the goal of improving the quality of clinical medical physicists and the profession. To achieve this objective, the IMPCB will accredit existing national/regional Medical Physics Certification Boards and encourage and assist those countries/regions that currently have no certification programs to develop them. It also works towards conducting certification examinations for medical physicists practicing where local certification is not currently available. The first tasks of the IMPCB were to develop a model certification program (published in 2011), write the By-Laws (adopted in 2012), and elect the 1st Board of Directors (took office in January, 2014). An Accreditation Committee was established with the initial task of development of the requirements for certification and accreditation (completed in November, 2014). These include requirements for general education (a minimum of a Masters degree), medical physics education (general and specialty), and clinical training. These requirements adhere closely to those published in IOMP Policy Statement No. 2: Basic Requirements for Education and Training of Medical Physicists, and several IAEA documents. Medical physics certification examinations might be in three parts: Part I (a written exam on general medical physics to be taken by all candidates), Part II (a written exam for each specialty), and Part III (an oral exam for each specialty). But the IMPCB recognizes that there are national/regional variations to certification in medical physics based on differences in national/regional legislation and educational traditions, so it gives to national and regional certification bodies considerable freedom to decide on the manner in which a given organization seeking IMPCB accreditation conducts the certification process. The Board decided to initially restrict accreditation of Boards and IMPCB certification examinations for only the three specialties Radiation Oncology Medical Physics, Diagnostic and Interventional Radiological Physics, and Nuclear Medicine Physics, and begin accepting applications for accreditation of national or regional medical physics certification boards in January, 2015. The Board also approved collaboration with the IAEA to work on certification of experienced medical physicists working in countries which currently have no certification Board. For the latter, a Question Bank has been developed for Parts I and II of the IMPCB certification examination.

In Canada designating Medical Physicists as a regulated health profession.

The purpose of this presentation is to report on the progress towards Medical Physics becoming a regulated health profession in Alberta.

Medical Physicists in Canada have a nationally recognized certification system through membership with the Canadian College of Physicists in Medicine (CCPM). While most Medical Physicist employers desire this membership or its equivalent, it is enforced only voluntarily by hiring institutions and managers. There is no legal requirement for membership with the CCPM to work as a Medical Physicist. Many of the clinical activities performed by Medical Physicists that can have direct clinical consequences for patients in terms of detecting and treating disease can be legally performed by anyone. This lies in contrast with many of our professional peers (physicians, radiation therapists, nurses, etc.), where provincial colleges independently define a scope of clinical practice, regulate those who may conduct that practice, and restrict the practice of certain activities to those registered with the college.

By defining a scope of practice and requiring members of a profession to meet and maintain minimum standards of competence, professional regulation ensures both patient safety and a minimum standard of care. Root cause analysis commonly identifies lack of Medical Physicist involvement, training, or qualifications as a significant contributor to major radiation therapy accidents and near misses. This suggests a key link between quality and safety and the regulation of Medical Physics.

In Alberta there are approximately 40 qualified medical physicists. For over five years the Association of Medical Physicists in Alberta (AMPA) has pursued professional regulation under Alberta’s Health Professions Act. In 2011, AMPA submitted an application for professional regulation to the Government of Alberta. Government feedback identified small physicist numbers as a primary barrier to regulation: the administrative workload of operating a professional college, and the cost of potential investigations and disciplinary committee hearings (involving legal council) were deemed prohibitive. However, subsequent feedback suggested the potential viability of a joint application with the Alberta Association of Clinical Laboratory Doctoral Scientists (AACLDS), an organization also seeking regulation, but limited by similar membership numbers. AACLDS represents professions including clinical chemists, microbiologists, geneticists, and toxicologists who share several professional similarities with medical physicists. Its members complete PhDs, then do two years of clinical training before writing a national certification exam. In the newly proposed model, Medical Physicists and the professions represented by AACLDS would join and be administrated by the College of Physicians and Surgeons of Alberta. The CPSA is a natural choice because (i) this college is the provincial accreditation body for ionizing radiation devices below energies of 1 MeV and (ii) our groups share common professional ground with physicians and surgeons, including a balance of clinical and academic responsibilities, and the extensive training involved in our professions.

At the time of this abstract submission, AMPA and AACLDS are in the process of submitting this joint application to the Government of Alberta. If successful, Alberta would become the first province in Canada designating Medical Physicists as a regulated health profession.

This talk will present an overview of the objectives of the International Medical Physics Certification Board (IMPCB), progress made since its formation, and the results of recent discussions to assure that the IOMP will play a major role in IMPCB governance in the future. The IMPCB was established in 2010 with the assistance of the Certification Task Group of the IOMP Professional Relations Committee, with the goal of improving the quality of clinical medical physicists and the profession. In Canada designating Medical Physicists as a regulated health profession.
**Materials and Methods:** The RPTP implemented is based on 6 educational modalities: (1) oral classroom presentations on general topics, (2) bimonthly bulletin publication distributed both electronically and on paper form, (3) computer-based training, basically interactive modules, with questions and answer to ensure and assess understanding of the notions developed, (4) posters display, (5) practical training on routine tasks and, (6) simulations of emergency situations in working environment. A registration methodology is used to verify the level of knowledge and competence of each worker to safely perform their job. After 5 years of the RPTP implementation, an internal audit was conducted with a 10-question survey designed with Survey Monkey to measure the training effectiveness and perception among users.

**Results:** Readiness of our informative bulletin alone is equal or higher than 70% for the past 4 years with highest rates among technologists. 73 people answered to the satisfaction survey, among them 74% were technologists, 11% were physicists, 11% were physicians and 2.7% and 1.3%, service techs and oncology residents respectively. The preferred educational supports were the interactive modules and the bulletin respectively, while posters are majorly disregarded. Interestingly enough, people are highly attached to classroom format and were very interested in emergency situations simulations. Respondents majorly stated to read the bulletin’s “always” for 68.5 % and “often” for 13.7%, independently of workers category. The answers are more divergent by work categories when asked about bulletin frequency appropriateness. Technologists are majorly satisfied with the actual bi-monthly rate while radiation oncologists are heaven distributed between status quo and frequency reduction. Contrariwise, for a majority of the physicists, frequency should be reduced. When asked about perception level of RP knowledge with regards to routine tasks, all physicists and physicians answered “adequate”. Answers were more mitigated among technologists where 68.5% answered “adequate”, 29.6% “basic” and 1.9% “thorough”. Interestingly, the commune highest confidence knowledge in all workers categories was found in RP specific to treatment machines, and the lesser in RP in non-medical related areas. Annual completion of electronic modules was majorly accepted.

**Conclusion:** As stated in the NSCA and other regulations, it is the licensee direct responsibility to ensure that workers receive appropriate training related to their specific jobs. Since its inception, the RPTP was well received and closely monitored. Users’ compliance and feedback helped to better meet their needs while continuously developing a radiation protection culture as proposed by the IRPA. It is possible to conclude that overall department stakeholders feel they have sufficient RP knowledge for their daily duties.

**Methodology**

2015 survey was sent to over 3200 contacts using WHO medical devices listserv tool. The survey was divided in four parts: country profile, educational institutions, professional societies and international organizations. Each part aimed to collect specific information on the topic and was aimed to be completed by the professionals holding section-specific information. Additionally a question regarding female presence within the profession was added in each section in order to measure the proportion of women actively working (in different sectors) or recently graduated in BME or related field. All collected information (including the four stages) is expected to be published in WHO Global Health Observatory (GHO), the World Health Statistics 2015 and ideally in ISCO-18.

**Results**

Research is ongoing but anticipates disclosing the presence of biomedical engineers by country (country profile), the number of educational institutions per country and the percentage of women actively present in the field. Additionally the presence of biomedical engineers in international organizations (e.g. UN agencies, Red Cross, development agencies, NGOs) and international professional societies is expected to be unveiled.

**Conclusion**

New information regarding the presence of biomedical engineers is now being collected and is aimed to be publicly available by June 2015. The dissemination and promotion of this information aims to strengthen biomedical engineering recognition in order to improve health care delivery.

**SP063.5 - Where to find biomedical engineers worldwide? Mapping biomedical engineers around the world**

**Author(s):** Daniela Rodríguez Rodríguez, Adriana Velazquez Berumen, Megan M. Smith, Ricardo X. Martinez

His/emp/pau/medical Devices, World Health Organization Headquarters, Geneva/SWITZERLAND

**Background**

Within health systems around the world trained and qualified biomedical engineering (BME) professionals are required to design, evaluate, regulate, acquire, maintain, and train on the safe use of the medical healthcare technologies. Nevertheless the profession is often left out from the health workforce in various countries, and biomedical engineers’ recognition and classification by the International Labour Organization (ILO) is still pending due to lack of statistical information of the current number of biomedical engineers around the world. Therefore with the intention of: a) promoting the role of biomedical engineering and related disciplines in healthcare, b) disseminating information about BME educational programmes and societies; and c) acquiring recognition of the profession at country/international level (e.g. International Standard Classification of Occupations (ISCO) by ILO) WHO started efforts to track biomedical engineers’ presence worldwide since 2009 and in four different stages: 1- 2009: in collaboration with the University of Campinas, work coordinated by professor S. Calli. 2- 2010: C. Long and R. Magiarevik 3- 2013-2014: D. Desai, J. Barragan, S. Mullally and N. Jimenez 4- 2015: on-going

On January 2015 WHO launched an extensive survey that aims to map biomedical engineers’ presence at a country level. Additionally information on existing professional societies, educational institutions in the field of BME and women’s role within the profession is being collected.

**Methodology**

By the end of 2013 Croatia’s health care sector had a permanent work force of about 74,500, around 13,750 medical doctors among whom approximately 9,700 specialists, and about 750 university degree health associates including clinical medical physicists and biomedical engineers. The objective of this paper is to present one national example of medical specialists grandfathering in favor of improved regulation of medical doctor profession, but all in wider context of global efforts towards better perception and regulation of clinical medical physics and biomedical engineering profession worldwide. Equal opportunities of continuing professional education and training, as well as career advancement (internship, residency, subspecialization, postgraduate specialist programs, etc.) should be facilitated and provided to all clinical scientists. Grandfathering is
certainly a usual step to give initial momentum, but grandfathering under the same criteria for all health professionals. For the maximal benefit of the patients, health professionals, health institutions and national health system, it appears that there is an urgent need in Croatia to make decisive actions towards much better perceiving and regulating the status of clinical scientists with background in natural, technical, biotechnical and social sciences.

SP063.7 - Biomedical Engineering Education and Training and Accreditation of Bachelor-degree Biomedical Engineering Programmes

Author(s): Min Wang
Department Of Mechanical Engineering And The Medical Engineering Programme, The University of Hong Kong, Hong Kong/HONG KONG

Hong Kong, like other advanced economies in the Asia-Pacific region, has an aging population and hence high-quality healthcare is required for its citizens. There is therefore an increasing demand for well-educated and well-trained biomedical engineers in Hong Kong. Hong Kong has a well-established system for tertiary education and professional training of engineers. In 2012 in Hong Kong, the British style 3-year university education was changed to the North-American 4-year one, giving local universities various opportunities for reforming their curricula, enhancing teaching and learning, improving student exchange programmes, etc. Biomedical engineering (BME) is a constantly expanding and intrinsically interdisciplinary field. The US and Western Europe as pioneers in the field have provided exemplary BME educational programmes. How to learn from these programmes and then set up their own programmes with distinct features for local students is not an easy task for BME educators in other countries. Currently, four universities in Hong Kong provide bachelor-degree level BME education: The Hong Kong Polytechnic University (PolyU), The University of Hong Kong (HKU), The Chinese University of Hong Kong (CUHK), and City University of Hong Kong (CityU). The 3-year curriculum BME programmes (which started in different universities at different times and will all end in 2015) in PolyU, HKU and CUHK have been fully accredited by the Hong Kong Institution of Engineers (HKIE) which is a signatory of the Washington Accord. The accreditation in Hong Kong of 4-year curriculum BME programmes was started in 2013, and in 2014 HKU’s 4-year curriculum Medical Engineering Programme became the first BME programme to gain HKIE’s provisional accreditation. (A BSc or BEng engineering programme can only gain provisional accreditation, not full accreditation, before it produces its first cohort of graduates.) Another university’s BME programme is currently going through the accreditation exercise. All 4-year curriculum engineering programmes put forward for HKIE’s accreditation must use the outcome-based approaches in student learning and hence the programme’s preparation for accreditation and the accreditation itself (criteria, documentation and presentation, process, etc.) are different for those used in the 3-year curriculum accreditation exercises. With these programmes as the foundation, a three-tier BME education is now in place in Hong Kong: the bachelor-degree level education (BSc or BEng), the taught-master degree (MSc), and research degrees (MPhil or PhD). Beyond the university education at these three levels, professional training in BME can be obtained in different organizations in Hong Kong. Government departments and the private sector alike contribute to BME engineer training. This presentation will give an overview of BME education and training in Hong Kong and briefly compare the BME programmes. It will also discuss various aspects of BME programme accreditation, drawing the author’s experience as the Programme Director to lead the HKU BME programme through its accreditation and also as the Visiting Team member for HKIE’s accreditation of a BME programme in another university.

SP063.8 - IOMP initiative for Validation and Accreditation of MSc courses

Author(s): Slavik Tabakov1, John Damilakis2
1Medical Engineering And Physics, King’s College London, London/UNITED KINGDOM, 2Medical Physics, University of Crete, Iraklion/GREECE

The Education and Training Committee (ETC) of the IOMP guides and supports a number of educational courses, workshops and projects around the world. One of these projects developed a Model Curriculum for post-graduate (MSc level) courses on Medical Physics. It also presented guidance on the organisation of such courses. The next stage of this activity is the initiative of international Validation and Accreditation of MSc courses in Medical Physics. These were briefly described in the book with educational experience from 26 countries (Medical Physics and Engineering Education and Training, available free from: http://www.emerald2.eu/mep/e-book11/ETC_BOOK_2011_ebook_s.pdf).

The Validation and Accreditation of MSc courses will be performed by the IOMP ETC. It will include assessment of the curriculum; assessment of the teaching methods; assessment of the examination process and assessment of the research activities (MSc project). The IOMP Model Curriculum will be used for the purpose and a number of expert medical physicists will be attracted to the validation process. The initial phase of the project will be guided in English and will be based on assessment of an English translation of the MSc Curriculum.

This IOMP activity will allow for a small country with limited expertise to set-up a post-graduate course in Medical Physics. This will boost the profession in many developing countries. The Validation and Accreditation of MSc courses will be used also for supporting the future Professional Certification of professionals. It is expected the first MSc courses to be accredited during 2015-16. The paper will present the application form and will discuss the application of the process.
Habiba Bougherara

Discussion:

3 modular necks (i.e. 39%, 31%, 30% change from intact femur from intact femur, p<.001) vs. short stem implants with any of the p>.05). Stress shielding existed for short and long stem implants Altering implant orientation had no significant advantage (α=.05, stem (slope=0.731, R=0.948) and long stem (slope=0.743, R=0.859).

Implants with shorter stems and longer necks have a greater chance reduce stress shielding. Results indicate some stress shielding in ing vs. long-stem implants. Anteverted and retroverted necks further ed into the femoral canal. Short-stem implants reduce stress shield ing vs. long-stem implants. Anteverted and retroverted necks further.

A finite element (FE) model employed laser scanned implants and a
axial loading in flexion, neutral, and extension phases of the gait
ditional femurs remained intact as controls. Femurs were mounted
ed, and retroverted – were assessed in each short stem. Three ad
ditional femurs remained intact as controls. Femurs were mounted
in cement blocks in 7 deg adduction and underwent quasistatic
axial loading in flexion, neutral, and extension phases of the gait
cycle. Strains were collected from surface-mounted strain gauges.
A finite element (FE) model employed laser scanned implants and a
previously validated femur model. Experimental strains were used to
validate the FE model. After validation, the full range of implant types
and physiologically possible orientations (i.e. varying anteversion
and anterior-posterior offset) were simulated (i.e. n=25 orientations
for each implant) under clinical-level loads. Stress was computed in
the calcar region and was compared between implants and across
each implant’s range of orientations. Stress shielding was the overall
stress change vs. an intact femur.

Results: FE model strains vs. experimental strains linear graphs showed an excellent fit for no implant (slope=0.898, R=0.943), short stem (slope=0.731, R=0.948) and long stem (slope=0.743, R=0.859). Altering implant orientation had no significant advantage (α=.05, p>.05). Stress shielding existed for short and long stem implants (p<.001), but was higher in the long stem implant (i.e. 63% change from intact femur, p<.001) vs. short stem implants with any of the 3 modular necks (i.e. 39%, 31%, 30% change from intact femur for standard, anteverted, and retroverted necks; p<.001 for differ ence between all stems except anteverted and retroverted). Long stems showed more distal-dominant stress transfer vs. short stems (p<.001), whilst peak stress was concentrated at the tip of the stem.

Discussion: Implant orientation via anteversion or anterior-posterior
offset does not alter stress shielding if the implant is properly insert ed into the femoral canal. Short-stem implants reduce stress shield ing vs. long-stem implants. Anteverted and retroverted necks further reduce stress shielding. Results indicate some stress shielding in correctly implanted hip stems in patients with realistic activity levels. Implants with shorter stems and longer necks have a greater chance of maintaining calcar bone strength, but these parameters may reduce short-term stability because of increased proximal loading.
There is currently no objective parameter to define bone fracture union. This makes it difficult for orthopedic care providers to properly treat fractures in areas that are prone to complications such as the tibial shaft. Additionally, the lack of an objective scale for fracture union complicates the comparison of the endpoints of various clinical studies on novel fracture treatments. The Radiographic Union Score for Tibial fractures (RUST) is gaining popularity as a standardisation of an objective parameter to be used in clinical practice and studies.

This study aims to validate RUST as a predictor of biomechanical properties of a fractured bone at different stages during healing using a rat model. A group of 45 male rats will undergo standardised osteotomy of the left tibia and the insertion of an unlocked and unreamed intramedullary nail. Orthogonal radiographs will be taken of the rat’s tibia on a weekly basis and each rat will be assigned a RUST score. The first 9 rats to reach RUST scores of 8, 9, 10, 11 and 12 respectfully will be sacrificed and the left tibia will be dissected. Subsequently, the intramedullary nail will be removed from the bones. The imaging and mechanical testing results will be compared with the rats’ RUST score and a score will be identified as a point when a bone can clinically be considered healed. This will allow for the standardization of an objective parameter to be used in clinical practice and studies.

Fractional flow reserve (FFR) is a well-known gold-standard for stenting decision in a coronary artery. Aim of this study is to present the influences of stenosis on pulsatile flow in multi-scale coronary modelling with virtual narrowing. A further purpose is to better understand the co-relation between fractional flow reserve and biomechanical factors for improving the decision-making strategy of stenting. In the present study, we present a patient-specific 3D coronary arterial modeling by coupled with lumped parameter coronary vascular bed outlet models. The computations of pulsatile flows in coronary artery were performed using a high-speed Navier-Stokes solver based on a finite element method. In this study, we analyse the haemodynamics in terms of various mechanical facetors (velocity, pressure, wall shear stress, etc.) with FFR and some other Index. Hybrid FFR-biomechanical factors could play a positive role on decision-making strategy for better diagnosis and prognosis.
SP065 - Conebeam CT

SP065.1 - Towards Functional C-arm CT Imaging in the Interventional Suite: Progress and challenges
Author(s): Rebecca Fahrig
Radiology, Stanford University, Stanford/CA/UNITED STATES OF AMERICA

When C-arm CT entered the interventional suite in the late 1990’s, the reaction from interventional radiologists ranged from ‘we don’t need it – we can easily create 3D images in our heads’ to ‘wow! that’s the first time I’ve been able to see that vessel clearly!’ Now, 3D C-arm CT imaging is done routinely during neuro- body- and even cardiac-interventional procedures. Technical advances in system components (faster rotation speeds, digital flat panel detectors with readout rates of 80 frames/s, variable trajectories) have enabled a progression from simple, high-contrast vessel imaging to detection of low-contrast soft-tissue lesions. It is now appropriate to explore what further advances are possible given the rapid evolution of the imaging hardware and software, and what these changes would bring to the interventional suite. We will examine these issues with the goal of providing functional information for intra-procedure and endpoint evaluation.

As a first step towards functional information, significant effort has been expended to improve the quantitative accuracy of C-arm CT reconstructions. The challenge is to improve image quality while providing very short turnaround between data acquisition and volume/data visualization. Corrections for x-ray scatter, view aliasing and patient motion that require no more than 2 iterations keep processing time short while reducing artifact. Additional challenges include detector non-linearity/saturation and restricted field of view.

Fast, multi-sweep acquisitions can be used to image blood flow in the brain and liver, permit assessment of left ventricular function, and visualization of radiofrequency lesions created to treat arrhythmias. Workflows for each imaging goal have been developed and validated against gold standard clinical CT or histology. The challenges, opportunities and limitations of the new functional imaging techniques will be discussed.

SP065.2 - 2D/3D Registration for Motion Compensated Reconstruction in Cone-Beam CT of Knees Under Weight-Bearing Condition
Author(s): Martin Berger1, Kerstin Mueller2, Jang-Hwan Choi2, Andre Aichert1, Andreas Maier3, Rebecca Fahrig2
1Pattern Recognition Lab, Department Of Computer Science, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen/GERMANY, 2Radiological Sciences Lab, Stanford University, Stanford/UNITED STATES OF AMERICA, 3Research Training Group 1773 “Heterogeneous Image Systems”, Erlangen/GERMANY

Introduction: Over the last decade, increased effort has been made to acquire three dimensional images of knee joints under weight-bearing condition. Cone-beam CT systems are popular because of their high flexibility with respect to patient position and scan trajectory. However, scans in a standing or squatting patient position are affected by involuntary patient motion during the acquisition, which results in streaking and blurring artifacts in the reconstructed volumes.

Previous work suggested the use of fiducial markers to estimate and compensate for motion artifacts. However, marker placement on the skin might not accurately reflect the motion at the center of the joint.

Method: We propose a marker-free, data-driven motion compensation method that is based on 2D/3D rigid registrations of segmented bones from a prior, motion-free scan.

The Figure above gives an overview of the pipeline of our method. The segmentations are roughly aligned in 3D with respect to an initial motion corrupted reconstruction. Motion parameters are estimated by 2D/3D registration of each bone to each projection image. After combining the individual bone motions to a global deformation, we can generate a corrected reconstruction.

Results and Discussion: To verify our approach we used a simulated dataset from previous work [1]. Our numeric phantom is based on segmentations of real anatomical structures. Real motion of healthy volunteers was incorporated into the phantom using an optical tracking system.

Our results show great improvement over images without correction. In particular the bones’ outlines are accurately restored. This is important because most relevant structures in the knee joint are located close to the bones, e.g., the cartilage. Incorporating smooth-
ness constraints into the registration cost-function further improved the results.

SP065.3 - Direct Scatter Estimation and Separation for Cone-beam CT Images Utilizing Monte Carlo Simulation

Author(s): Yu Wang, Chaobin Chen, Ruifen Gao, Lijun Hu
University of Science and Technology of China, Hefei/CHINA

Objective: The scatter radiation degrades the reconstructed Cone-beam CT(CBCT) images quality, which limits the application of CBCT images into the re-optimization of treatment plans for Adaptive Radiotherapy (ART). This paper estimated the scatter distribution in the CBCT projections directly utilizing the Monte Carlo simulation. In addition, the scatter separation was taken into account to determine the corresponding scatter fraction introduced by different parts of the system.

Methods and Materials: Using EGSnrc Monte Carlo program, the ELEKTA XVI CBCT system was modeled including the x-ray tube, water phantom with different thickness and flat-panel detector. The LATCH option was adopted to record the particles information, including the fluence, energy, weight, weather a secondary particle and which modules it had interacted with. The model was validated by percentage depth dose (PDD) and lateral profiles measurements. A program based on Visual C++ was developed to extract the primary particles and calculate the total scatter radiation at the scoring plane. At last, the corresponding scatter fractions introduced by different parts of the system were separated.

Results: The calculated PDD and lateral dose profiles were compared against the dose measurements under 1cm water. The dose difference of PDD was better than 1% within the depth of 10cm. More than 85% points of lateral dose profiles was within 2%. For CBCT system, the phantom produced the larger part of the scatter radiation, almost 50% with water thickness of more than 25cm.

Conclusions: The CBCT system has been fully modeled including x-ray tube, phantom and flat-panel detector and the model was validated by the PDD and lateral profiles measurements. The scatter fractions introduced by the phantom with thickness of more than 25cm should be corrected to improve the images quality. This study is expected to be applied to the scatter radiation correction for improving CBCT images quality and optimizing the CBCT modules design.

SP065.4 - Automatic Motion Estimation and Compensation Framework for Weight-bearing C-arm CT scans using Fiducial Markers

Author(s): Kerstin Mueller, Martin Berger, Jang-Hwan Choi, Andreas Maier, Rebecca Fahrig
1Radiological Sciences Lab, Stanford University, Stanford/CA/UNITED STATES OF AMERICA, 2Research Training Group 1773 "Heterogeneous Image Systems", Erlangen/GERMANY

Cone-beam CT systems are widely used because of their high flexibility with respect to patient position and scan trajectory. In the last years, C-arm CT systems have been used to acquire images in weight-bearing conditions in order to expose, e.g. the knee joint under realistic loads. Straight standing or squatting patient positions lead to involuntary patient motion during the acquisition. In this paper, a fully-automatic motion estimation and compensation framework to mitigate knee-joint motion during weight-bearing C-arm scans is presented. Our framework consists of three major steps: marker detection with outlier removal, motion estimation and correction, and marker removal. The marker detection is based on an initial estimate of the marker position extracted from the motion-blurred filtered backprojection (FDK) reconstruction and on the fast radial symmetry transformed (FRST) 2-D projection images. The motion is estimated by the alignment of the forward projected 3-D initial marker positions with the actual detected 2-D marker positions. The motion is then corrected in the filtered backprojection step. Finally, the detected markers are removed in the 2-D projection images by simple interpolation. The framework was evaluated on three C-arm CT datasets from one volunteer in a straight standing, moderate squatted and deep squatted position. All 3-D reconstructions show a large improvement in image quality compared to the non-corrected 3-D reconstructions.
SP065.5 - Evaluation of two-pass view aliasing artifact suppression algorithm using clinical data
Author(s): Meng Wu, Kerstin Mueller, Michael P. Marks, Rebecca Fahrig
1Department Of Radiology, Stanford University, Stanford/UNITED STATES OF AMERICA, 2Department Of Radiology And Neurosurgery, Stanford University, Stanford/UNITED STATES OF AMERICA

Purpose: In brain perfusion CT imaging, state-of-the-art C-arm CT systems can rotate up to 100 degrees / second, which permits CT imaging with high temporal resolution. However, the read-out rate of the flat panel detector often limits the number of projections acquired in the fast scan and causes view aliasing artifacts in the reconstruction. We propose to suppress aliasing artifacts in decomposed projections through feature preserving interpolation.

Methods: The high frequency structures that cause streak artifacts are hidden within the total line integral. Thus, the interpolation-based method for angular up-sampling often fails to correct for these high frequency structures. We propose an FBP-based algorithm using multi-resolution reconstruction to identify the structures in projection space that may cause the artifacts. The adaptive multi-resolution FDK reconstruction adaptively selects the bandwidth of the ramp filter in the FDK method to reconstruct regions of the image at maximal frequency without view aliasing artifacts. A feature preserving interpolation in projection space is used to increase the angular sampling rate. The restored high frequency structures are then added back to the view aliasing-free reconstruction. The proposed method’s performance is assessed using real patient C-arm (Artis zee biplane system, Siemens AG, Germany) head scan data. Only 124 out of 248 projections are used for the reconstruction to mimic the sparse-view data in the fast scan. Our results are compared to those with and without linear interpolation method.

Results: As shown in Figure 1, the proposed method can effectively reduce the view aliasing streak artifacts. The structural similarity (SSIM) indices of the brain tissue region using the FDK, linear interpolation, and proposed methods comparing to the ground truth are 0.7428, 0.7686 and 0.8060, respectively. The proposed method also reduces the standard deviation of the brain tissue without contrast (which is assumed to be uniform) from 56.2 HU to 35.7 HU while the linear interpolation method has a standard deviation of 42.5 HU. The proposed method is compatible with a projection-based motion compensation technique to further improve the image quality.

Conclusion: Distinct from other blurring-based and iterative reconstruction methods, our method maximally preserves image spatial resolution with only two iterations. Future investigations will incorporate the technique for noise reduction and compare to sparse view iterative reconstruction.

Figure 1, reconstruction results using FDK, linear interpolation and the proposed method. The display window is [-500 500] HU.

SP065.6 - A simple algorithm to remove metal artifacts in frame based radiosurgical treatments
Author(s): Gopishankar Natanasabapathi
Gamma Knife Unit, All India Institute of Medical Sciences, New Delhi/INDIA

Purpose: To show a simple method to remove metal artifacts generated during imaging for treatment planning purpose. Materials and Methods: A human head shaped phantom made from acrylic material was fixed to stereotactic Leksell frame for artifact simulation purpose. Four metal screws aided in holding the metal frame to the phantom with carbon fixation posts. An ion chamber positioned in the middle portion of the phantom determines point dose measurement. In this study same ion chamber setup generated artifacts at the phantom center which required artifact removal. CT scans of the phantom were acquired using following scanning parameters: Tube voltage-110 kV, Slice thickness-1 mm and FOV-240 mm. Image slices with severe artifacts were selected for image processing using in-house developed matlab codes. Pixels in the phantom image affected by noise were isolated and digitally post processed by applying threshold value to the hounsfield units (HU).

Results: The images showed more than 95 % improvisation after implementing correction algorithm. Before image correction the HU present in the phantom image due to metal frame and pins was found to be more than 3000 HU. After applying correction algorithm, HU of ion chamber region, metal frame and pin region were restored.

Conclusion: The TPS system of Gamma Knife (GK) performs convolution algorithm based calculation on CT images with HU values range between -1000 to +1024. Any HU values beyond these values are automatically ignored by the TPS during calculation. It means that the TPS ignores the artifact affected region for calculation irrespective of where it is present. This is one of the major limitations of convolution algorithm based planning in GK. The artifact removal method shown in this study is a simple, effective technique which overcomes these limitations and is a valuable tool for GK.
SP066.1 - Fingertip touch adjust postural orientation during perturbed stance  
**Author(s):** Aizreena Azaman, Shin-Ichiroh Yamamoto  
Department Of Bioscience And Engineering, Shibaura Institute of Technology, Saitama City/JAPAN

Additional sensory information; especially from touch, was suggested to improve stability by reducing body sway. However, it is less known about the effect of touch on the body’s joint movement during perturbed standing; which is commonly experienced by public transport users. In this study, subjects were asked to try to maintain their standing position with their fingertips on a rigid surface, while surface perturbation was applied at four different perturbation frequencies (0.2, 0.4, 0.6, and 0.6 Hz) and different vision input. Motion of joint (ankle, hip and head) and relative centre of mass (COM) were recorded and analysed. The results show that fingertip pressure was higher without vision. Furthermore, different fingertip moment directions were recorded between with vision and with no vision. This possibly indicates a preferred fingertip position that can provide better sensory information to replace sensory loss; especially vision. The range of motion of joints also decreased with fingertip touch - except for head motion. Furthermore, even though there were no significant differences observed between with touch and without touch, the relative COM displacement was less with touch. Thus, even with a very light touch, subjects were able to reduce body sway even in a perturbed stance. Further investigation is needed to determine the changes in centre of pressure (COP) and significant position of fingertip, which can enhance stability.

SP066.2 - Design and Evaluation of a Prosthetic Knee Joint based on Automatic Stance-Phase Lock (ASPL) Technology for Children with Transfemoral Amputations  
**Author(s):** Calvin Ngan, Jan Andrysek  
Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto/ON/CANADA

**Introduction:** Lower extremity amputation strongly affects an individual's mobility and quality of life, as well as creating a socioeconomic burden for society. Studies have shown that amputations in children have a particularly significant impact on their physical and psychological developments. Therefore, it is important to provide child amputees with a well-functioning prosthetic knee joint to restore their mobility function and enable them to partake in physical activities with peers and family.

**Problem:** Many paediatric prosthetic knee joints in the market incorporate four- or six-bar linkage mechanisms that offer good stance phase control, but their added size and weight make them unsuitable for very small children. Furthermore, to accommodate these size constraints, many designs exclude swing phase control and extension assist mechanisms, negatively impacting user’s gait characteristics such as energy expenditure and gait speed. Therefore, the objective of this project is to design and evaluate an original paediatric prosthetic knee that will provide good stance phase stability by incorporating the novel, patented Automatic Stance Phase Lock (ASPL) mechanisms developed in Holland Bloorview Kids Rehabilitation Hospital, and integrating frictional components and extension assist mechanism to offer better swing phase control for the user.

**Method:** We focus on three major areas: (1) knee design and proto-
type development, (2) structural testing, and (3) functional evaluation via a pilot study. We will use 3D Computer Aided Design (CAD) and Finite Element Analysis (FEA) software to develop and structurally optimize the prosthetic knee joint model. A prototype will then be constructed and a series of bench-top structural tests will be performed following the ISO 10328 to test for structural integrity. In the pilot study, a single subject with an unilateral transfemoral amputation will perform six-minute walk tests and gait assessment tests with his/her current prosthetic knee, as well as our prototype. Gait characteristics such as walking velocity, kinetics profiles including knee flexion angle and knee moment, and energy expenditure will be measured and analyzed in both trials. Differences in the key parameters listed above between the prototypes and the conventional knee will be used as an indicator for how functional the prototype is and indicate which design changes may improve areas of concern.

**Results:** In the current stage of the project, we designed and developed a 3D computer model of the paediatric prosthetic knee. In the model, our prototype is estimated to be 120mm tall and weighs about 355g, which is similar to current commercially available products. It also includes mechanical friction control and extension assist to facilitate the swing phase control for the user. Multiple iterations of FEA on the model were completed, and the results suggested that the design is capable of supporting the specified load listed in the ISO structural test. Therefore we will proceed to fabricating the prototype and performing the structural test imminently. The goal of this project is to prove the feasibility of implementing ASPL technology in a paediatric prosthetic knee, so ultimately it would be possible to provide well-functioning and affordable prostheses for child amputees around the globe.

**SP066.3 - Frontal plane gait during cross-slope walking for able-bodied and transtibial amputees**

**Author(s):** Emily Sinitski, Edward D. Lemaire, Nancy L. Dudek, Markus Besemann

1Crrd, The Ottawa Hospital Research Institute, Ottawa/CANADA, 2Faculty Of Medicine, University of Ottawa, Ottawa/CANADA, 3Canadian Forces Health Services Group, Ottawa/CANADA

Cross-slope surfaces are slopes in the frontal plane. Unlike level and inclined surfaces, cross-slope walking requires an asymmetrical gait pattern to keep the body vertical while adapting to different ground heights and angles. Although cross-slopes are a common real-world surface, cross-slope walking literature is predominately on the able-bodied population. For individuals with a lower limb amputation, lack of lower limb musculature may pose a greater challenge for maintaining balance and forward progression on cross-slopes. This research investigated compensatory adaptations in the frontal plane for able-bodied individuals and individuals with a transtibial amputation when walking on moderate cross-slopes.

Fourteen able-bodied (AB) and 14 unilateral transtibial amputees (TTA) participants in this study. Participants walked on a level and +5° cross-slope treadmill at a fixed speed while full body kinematic data were captured within a CAREN-Extended virtual reality environment. Gait outcome measures included, speed, step width, and frontal plane joint angles (ankle, knee, hip, pelvis, and trunk) and sagittal plane joint angles (ankle and knee) at foot contact and during stance. Data were examined using a linear mixed model with a treadmill speed covariate. Post-hoc t-tests with a Holm-Bonferroni correction (p<0.05) were performed to examine differences between groups and walking conditions.

TTA participants walked slower than able-bodied (AB = 1.29±0.06 m/s, TT = 1.11±0.15 m/s; p<0.001). Step width (14.7±0.6cm) was not significantly different between walking conditions and groups. Compared to level walking (LW), the limb at the top of the cross-slope (TS) had less ankle inversion at foot contact and ankle angle trans-}
SP066.5 - The influence of the aquatic environment on the control of gait initiation

Author(s): Andresa Marinho Buzelli, Hossein Rouhani, Gustavo Fernandes, Kei Masani, Milos Popovic, Molly Verrier

1Rehabilitation Engineering Laboratory, Toronto Rehabilitation Institute - University Health Network, Toronto/CANADA, 2Universidade Federal de Santa Catarina, Florianopolis/BRAZIL, 3Toronto Rehabilitation Institute - University Health Network, Toronto/CANADA, 4Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA

**Background:** Gait initiation is a common functional task defined as the transition from stationary standing to steady-state walking. It is vastly investigated in healthy subjects and in individuals with disability. The complex interaction between neuromuscular and biomechanical factors during gait initiation has been investigated mainly in two phases, anticipatory postural adjustments (APAs) and execution of the step. Despite the frequent use of therapy pools for walking training in early stages of locomotor recovery, the effects of immersion on the control of gait initiation have not been reported yet. The objective of the present study is to analyze the center of pressure (COP) trajectories, the vertical and horizontal forces and trunk acceleration (ACC) during APAs, as well as during execution of the first and second steps during gait initiation.

**Method:** Able-bodied young adults (3 female and 2 male) were requested to initiate gait from a waterproof force plate (AMTI OR6-WP-1000, Watertown) and to continue walking for 5 steps. Individuals performed 10 consecutive trials, on land and in water, on two consecutive days. Subjects initiated gait with the same foot position following a visual cue. Two inertial sensors (Physilog, BioAGM, Lausanne) were attached to L5/S1 vertebrae and to the shank of the initial stance limb. COP landmarks were used to identify APAs and execution of the first step. Shank ACC was used to mark the toe-off and heel strike of the second step. Lower trunk (LT) horizontal ACC (anteroposterior – AP and mediolateral – ML) during APAs and execution phases was computed. The parameters used for evaluation were: peak of anticipatory COP trajectory (APA_Peak); COP length during APAs; length and velocities of COP trajectories during execution of the first step; impulse forces in vertical and AP directions; root mean square (RMS) ACC of trunk during first and second steps. Wilcoxon Matched-Pair Signed-Rank test was used for comparisons between land and water conditions.

**Results:** Percentage of body mass offloading in water varied between 49% and 57%. COP movements during APA and execution of first step were significantly larger in water compared to land: APA_Peak in ML (5.1±1.7 vs. 3.7±1.5 cm); ML length of COP trajectory when body weight was transferred to the stance limb (22.8±4.2 vs. 18.2±3.5 cm); and ML length of COP during first swing (5.4±1.8 vs. 2.8±1.1 cm). COP velocity in AP during the first swing was slower in water (16.7±4.2 vs. 26.7±4.9 cm/s). The vertical impulse of the stance limb was smaller in water compared to land (340.7±31.1 vs. 425.4±54.2 N.s). LT ACC were smaller in water compared to land with more accentuated change in AP RMS of LT ACC during first step (0.6±0.3 vs. 1.8±0.7 m/s²) and second step (0.7±0.2 vs. 1.6±0.3 m/s²).

**Conclusion:** Immersion in water increases mediolateral body displacement, and reduces trunk acceleration and vertical impulse force during gait initiation, suggesting potential implications for aquatic rehabilitation.
SP067 - Characterization of Detector Systems for Therapy Dosimetry: Part 2

SP067.1 - Reaction of three UV exposure to gafchromic EBT-2 and EBT-3

Author(s): Toshizo Katsuda¹, Rumi Gotanda², Tatsushi Gotanda³, Takuya Akagawa⁴, Nobuyoshi Tanki⁴, Tadao Kuwano⁵, Kouichi Yabunaka⁶

¹Department Of Human Relation, Tokai Gakuin University, Kaka-migahara/JAPAN, ²Department Of Radiological Sciences, Ibaraki Prefectural University of Health Sciences, Ibaraki/JAPAN, ³Department Of Radiological Science, Faculty Of Health Sciences, Junshin Gakuen University, Fukuoka/JAPAN, ⁴Department Of Radiological Technology, Tokushima Red Cross Hospital, Tokushima/JAPAN, ⁵Center For Life Science Technologies, RIKEN, Kobe/JAPAN, ⁶Graduate School Of Health Sciences, Okayama University, Okayama/JAPAN, ⁷Graduate School Of Medicine, Tokyo University, Bunkyou-ku/JAPAN

Gafchromic films (GAFs) are used for the X-ray dose measurement in the diagnostic examination. It is begun to use for the three-dimensional X-rays dose measurement using the high-resolution characteristic in computed tomography. However, it is necessary to solve a problem of unevenness of active layer of GAFs. It is suggested that the ultraviolet (UV) is substitute as an X-ray. However, wavelength of appropriate UV are unidentified. This study is to decide a wavelength of the UV.

Peak wavelength of 245 nm, 310 nm and 365 nm UV were irradiate to the EBT2 and EBT3. The UV rays were irradiated for 5, 15, 30 and 60 minutes, and irradiation was repeated afterwards until 360 minutes every 60 minutes. The images were split in RGB, and R images were used. ROI of the diameter 1/2 inch was set in the center of subtracted GAF images, and the graph of UV irradiation time and the mean pixel value were made.

There was a reaction in front and back of GAF EBT3 and back of EBT2 in UV-A and B. However, UV-C had few reactions with both aspects of GAF EBT2 and EBT3.

It should be used UV-A for a fact because a wavelength of UV-B may affect the human body.

SP067.2 - Characterizing FujiFilm CR Signal Storage Decay Rates

Author(s): Thorarin A. Bjarnason¹, C J. Yang²

¹Diagnostic Imaging Services, Interior Health, Kelowna/CANADA, ²Sindi Ahluwalia Hawkins Centre For The Southern Interior, British Columbia Cancer Agency, Kelowna/CANADA

Introduction

In this work we outline a method for characterizing x-ray signal retention on Fujifilm CR photostimulable phosphors (PSPs). In order to use CR plates as dosimeters and to ensure the accuracy of image quality and dose indicator metrics, the behavior of x-ray signal storage needs to be characterized. Based on electron-hole storage of PSPs, it is known that in addition to specific frequency light stimulation overcoming the band gap and releasing the stored signal, thermal processes can do likewise, but at slower rates [Rowlands].

Methods/Results

The same FujiFilm CR plate was exposed repeatedly to 700 (±20) uGy at 120kVp and readouts were spaced out between immediate and 20days, as shown as the blue dots in A. Raw pixel values were extracted from image data and converted to dose as per [Bjarnason1]. When exposures were performed on separate days, all data were normalized using image data scanned immediately on that day. CR plates were sandwiched between 4 mm lead to minimizing background radiation exposure during the measurement time delay. The resulting decay was fit (black line in A) using a sum of exponential decays as per [Bjarnason2], which makes no a priori assumptions as to the number of exponentials present. The resulting relaxation distribution was found (B) and the following decay components were identified: 0.014 @ 2.8min, 0.045 @ 10.3min, 0.126 @ 2.1hr, 0.046 @ 15.9hr, 0.48 @ 40days.

Discussion/Conclusions

In this work we characterized 20 days of CR signal retention. Signal fading of 25% is expected between 10min and 8hr, and then slower after [AAPM 93], but this behavior has not been fully characterized before. We found the signal decay to be multiexponential and can conclude that the first two decay components at 2.8 and 10.3min should minimally affect the CR dose indicator values because even though staff often quickly read the images while signal is being lost due to these decay times, their intensities only account for 5% of the total signal loss occurring after about 1hr. By characterizing the signal loss over longer times, we can use these data to calibrate CR plates for use as area dosimeters. Future work includes testing inter-
plate variability, assessment at different kVps, and assessment of different vendors using different PSP chemical compositions.

SP067.3 - Angular dependence of diode detectors and PinPoint ionization chamber in Gamma Knife dosimetry

Author(s): Hrvoje Hršak1, Marija Majer2, Zdravko Heinrich3

1Department Of Oncology, University Hospital Centre Zagreb, Zagreb/CROATIA, 2Laboratory For Radiation Chemistry And Dosimetry, Institute Ruđer Bošković, Zagreb/CROATIA, 3Department Of Neurosurgery, University Hospital Centre Zagreb, Zagreb/CROATIA

Dosimetry for Gamma-Knife radiosurgery beams requires detectors with high spatial resolution, minimal angular dependence of signal and linear dose response. Angular dependence for shielded (PTW60016 Diode P) and unshielded (PTW60017 Diode E) p-type silicon detectors and PTW31006 PinPoint ionization chamber was measured indirectly with 18, 14, 8 and 4 mm collimator for the Leksell Gamma Knife Model C. Weighted angular dependence correction factors were calculated for each detector and collimator helmet. For Gamma-Knife beams angle range of 84°-54° Diode P detector shows considerable angular dependence of 9% and 8% for the 18 mm and 14, 8, 4 mm collimator, respectively. For Diode E detector this dependence is about 4% for all collimators. Compared to Diode E, Diode P shows stronger angular dependence which may be explained by the increase of electron backscattering from the metal shield of silicon active volume as the angle of incident photon beam decreases, i.e. more photons are entering silicon chip perpendicularly. PinPoint ionization chamber shows angular dependence of less than 3% for 18, 14 and 8 mm helmet and 10% for 4 mm collimator which is probably due to volumetric averaging effect in a small photon beam. Diodes P and E represent good choice for Gamma-Knife dosimetry, while PinPoint ionization chamber is not recommended for dosimetry with the 4 mm collimator helmets. When used for absolute and relative dosimetry of Gamma Knife beams, diodes and PinPoint ionization chamber response should be corrected for angular dependence.

SP067.4 - Determination of a correction factor to mitigate long term reader fluctuation of the Optically Stimulated Luminescence dosimetry system at the International Atomic Energy Agency

Author(s): Andrew Cole, Tomislav Bokulic, Paulina Grochowska, Joanna Tzewska

Nuclear Sciences And Applications, International Atomic Energy Agency, Vienna/AUSTRIA

Introduction

The Dosimetry Laboratory at the International Atomic Energy Agency is commissioning an Optically Stimulated Luminescence (OSL) dosimetry system to provide radiotherapy dosimetry audits. The OSL readers’ (Microstari, Landauern) internal mechanism consists of a high powered light emitting diode (LED), optical components and a photo-multiplier tube (PMT). Inbuilt PMT response Quality Assurance checks along with standard measurements from control OSL dosimeters allow the daily performance of the readers to be monitored. Extensive measurements were conducted during a period of 6 weeks. In this time the PMT response showed a fluctuation of 1.7% and the control OSL dosimeters’ results exhibited a fluctuation of 1.4%. A correction factor to mitigate this magnitude of reader fluctuation is necessary and was calculated with two separate methods.

Materials/Methods

In the first method, PMT response QA checks were periodically performed directly preceding measurements of a control batch of OSLDs. A linear correlation of the magnitude of deviation of OSL dosimeter readout values from postulated theoretical values, as demonstrated on an earlier model system [1]. These deviations were deemed attributable to reader fluctuations and the magnitude was correlated to PMT response data to determine a correction factor. In an iterative approach, this method also allowed a more accurate theoretical model to be calculated.

Results

Reader fluctuation correction factors were determined by both methods and applied to daily control OSL dosimetry data. The two methods of determination of reader fluctuation correction factors resulted in reduced long term fluctuation in control OSL readout values to 0.9% and 0.2%, respectively, over the 6 week period. Longer term investigation may allow this to be improved as more data is acquired.

Conclusion

To mitigate the influence of long term reader fluctuation on the determination of OSL dosimetry audit values, a reader correction factor has been determined from two methods. The application of this correction factor has achieved a substantial decrease in the magnitude of reader fluctuations over a period of 6 weeks and will be the basis of protocols to also reduce fluctuation on the short term.

SP067.5 - Reference and relative dosimetry of standard and small photon fields with new commercially available detectors

Author(s): Bryan R. Muir, Malcolm R. Mcewen

Measurement Science And Standards, National Research Council, Ottawa/CANADA

Two new detectors, the PTW microDiamond synthetic diamond detector and the Exradin W1 plastic scintillation detector (PSD), are now available that were designed for the dosimetry of small radiation fields. We investigate the performance of a single version of each detector when used for reference dosimetry of standard fields and relative dosimetry of small fields placing specific emphasis on the determination of associated uncertainties.

Measurements of detector response are made under reference conditions in 6, 10 and 25 MV photon beams from the Elekta Pre-
cise linear accelerator in 10x10 cm² field sizes relative to secondary standard reference chambers, calibrated in terms of absorbed dose directly against the National Research Council of Canada (NRC) primary standard water calorimeter. These absolute calibrations are used to derive detector energy dependence as well as short- (hours) and long- (months) term repeatability. Profiles are measured with these detectors in fields as small as 0.6x0.6 cm² shaped by the Elekta photon jaws and used for accurate detector positioning in small fields. Once detectors are properly positioned on the beam axis, small field output factors are measured, keeping the detector position constant and modifying the photon jaw settings. Measurements of output factors are repeated to investigate uncertainties caused by jaw positioning repeatability, detector positioning and the repeatability of the detector response and/or associated noise.

For both detectors, energy dependence is less than 1% comparing calibrations over the range 6-25 MV. The repeatability of the PTW microDiamond response for calibrations under reference conditions is within 0.3% after a period of almost two months. The repeatability of the response of the Exradin W1 PSD is generally also at this level, although sometimes unexpected differences of 1-2% were observed, which require further research for explanation. Profiles measured with the two detectors are in good agreement although the very small signal from the Exradin W1 is much noisier. The attached figure shows small field output factors (i.e., readings normalized to the value obtained in a 10x10 cm² field) with error bars representing type A uncertainties and variations in repeated measurements of output factors. For both detectors, standard uncertainties in reference dosimetry measurements are within 0.4% and are less than 2% for relative dosimetry measurements in very small fields.

Both detectors investigated in this work exhibit very impressive behavior for both reference and relative dosimetry measurements.

SP067.6 - Evaluation of detectors response for small field output factor measurement using multichannel film dosimetry

**Author(s):** Gunther Rucka, Jean Claude Mouttet, Nathalie Asquier, Patrice Budillon

**Centre De Radiothérapie St Louis, Croix-Rouge Française, Toulon/FRANCE**

**Introduction**

Most irradiation technics require dose computing from TPS. Calculation accuracy highly depends on the measurements used for beam modeling. Depending on their characteristics, available detectors may be best suited for specific field sizes when measuring Output Factors (OF). Recent studies compare several active with passive detectors and Monte Carlo calculation.

The goal of our study is to evaluate the response of several active detectors exposed to 6 MV X-ray beams of different sizes, down to 1x1 cm², while considering EBT3 Gafchromic films as reference.

**Materials and methods**

Eight EBT3 films were irradiated with field sizes ranging from 1x1 to 10x10 cm². Measurements were done in a home-made RW3 solid water phantom. Multichannel film dosimetry was used for film opacity-to-dose conversion. All films (including background) were irradiated and scanned simultaneously using the efficient protocol described by D. Lewis et al.

Among available active detectors, two ionization chambers and two diodes were studied. Measurements were carried out in a water phantom.

OF measurements were also done by placing both chambers in the solid water phantom, in the same condition as the films. Results were compared to measurements done in water in order to verify scattering components correspondence for all field sizes. This allows active detectors irradiated in water to be compared to the films in RW3 slabs.

**Results**

OF obtained with the ionization chambers placed in the water and solid water phantom are identical for field sizes smaller than 15x15 cm².

As described in P. Andreo publication, active detector response for each field size was normalized with respect to the reference data. Figure 1 shows results. Concerning ionization chambers, the influence of partial volume averaging is similar to the published results. The three major effects mentioned for the diodes also appear in our results: the charged particles equilibrium between detector material and water, the over-response of the unshielded diode in broad beams and the partial volume averaging.

**Conclusion**

Our study confirms that partial volume averaging is not the only undesirable effect for OF measurement. Thus, the detector having the best spatial resolution is not systematically the best suited for small fields OF measurements.
SP068 - Development of New Methods in Therapy Dosimetry

SP068.1 - A Farmer ion chamber as reference to the calibration of CT chambers

Author(s): Ricardo A. Terini1, Marco A. Guedes Pereira2, Maria Carolina S. Campelo1
1Depto. De Fisica, Pontificia Universidade Catolica de Sao Paulo, Sao Paulo/BRAZIL, 2Laboratorio De Ensaios Nao-destrutivos, Instituto de Energia e Ambiente, Universidade de Sao Paulo, Sao Paulo/BRAZIL

Introduction: Computed tomography (CT) is among the largest sources of collective radiation dose. The absorbed dose in CT exams can be ten times higher than in other common procedures of radiographic imaging. To assess the dose of radiation, the necessary meters should be properly calibrated in beams and setups like those measured in field [IAEA, Dosimetry in Radiology: An International Code of Practice, TRS 457, 2007]. AAPM TG111 report [AAPM, Comprehensive methodology for the evaluation of radiation dose in X-ray computed tomography. AAPM report 111, 2010] has proposed improved metrics for CT dosimetry, using a small ion chamber, mainly considering helicoidal and multislice scanning. This study aimed to improve the methodology for CT ion chamber calibration in standard dosimetry laboratories, inspired on IAEA and AAPM recommendations.

Methodology: Initially, CT standard beams (RQT) have been characterized, using a calibrated PTW Farmer chamber as reference. Then, we have investigated some options to the setup to calibrate CT “pencil” type chambers in Air kerma-length product (PKL) by substitution: without any collimator (A) or with a reference collimator of aperture L=2cm (B.2) or L=5cm (B.5) in front of the chamber to be calibrated (Fig.1). Additionally, homogeneity of the pencil chamber response was checked shifting the chamber perpendicularly to the beam, behind the collimator, 1 by 1cm, and repeating the calibration with B.2 setup.

Results and Discussion: Table 1 summarizes the obtained results for 100mm PTW chamber calibration coefficients. Results showed differences up to 2% in the obtained calibration coefficients, depending on the aperture of the used collimator. In the following additional tests, pencil chamber homogeneity just kept up to 3.5cm from the chamber center. Results were very similar for other CT chambers from Radcal Co.

SP068.2 - Determination of the Uncertainty in the Cross-calibration of an Ionization Chamber Used in Radiation Therapy

Author(s): Pedro H.B. Cardoso1, Wellington F.P. Neves-Junior1, Gustavo F. Tietz1, Cecilia M.K. Haddad1, Ricardo A. Terini2
1Radioterapia, Sociedade Beneficente de Meninas Hospital Sírio-Libanês, São Paulo/BRAZIL, 2Depto. De Fisica, Pontificia Universidade Católica de Sao Paulo, Sao Paulo/BRAZIL

It was performed an analysis of the uncertainties involved in a cross-calibration procedure of an ionization chamber used in Sírio-Libanês Hospital, according to the methodology proposed in IAEA-TECDOC-1585, based on ISO GUM. The overall uncertainty obtained was 2.55% (coverage factor k = 2), which meant an increase of 0.04% compared to the reference ionization chamber uncertainty reported by the dosimetry laboratory of LCI-GMR-IPEN/CNEN-SP. In such cases where the uncertainty of the calibration coefficient of the reference instrument is high, this uncertainty dominates the overall uncertainty of the cross-calibration. It was performed an analysis of the uncertainties involved in a cross-calibration procedure of an ionization chamber used in Sírio-Libanês Hospital, according to the methodology proposed in IAEA-TECDOC-1585, based on ISO GUM. The overall uncertainty obtained was 2.55% (coverage factor k = 2), which meant an increase of 0.04% compared to the reference ionization chamber uncertainty reported by the dosimetry laboratory of LCI-GMR-IPEN/CNEN-SP.
SP068.3 - A study of uncertainties in the half-value layer measurement of a miniature kV x-ray source

Author(s): Peter G. Watson, Marija Popovic, Jan Seuntjens
Medical Physics Unit, McGill University, Montreal/CANADA

Air kerma standards for low energy x-ray devices used in electronic brachytherapy or intraoperative radiotherapy critically depend on accurate knowledge of the primary spectrum of the source. A model of a low energy x-ray source (INTRABEAM, Carl Zeiss) using the EGSnrc Monte Carlo (MC) code has been developed. To validate the model in-air, half-value layer (HVL) attenuation measurements were performed and compared with calculated values. For a meaningful comparison, the uncertainties in both the calculated and measured HVL must be well understood. In this work, we discuss the statistical and systematic uncertainties in HVL calculation.

The INTRABEAM source was modeled using the EGSnrc user code cavity. Photon fluence spectra emitted by the source were scored for the bare probe and spherical applicators of 3.5 cm, 4.0 cm, and 4.5 cm diameter. HVL was determined analytically from the simulated spectra by calculating the attenuation of air-kerma for a given thickness of aluminum and source-to-detector air gap. Beam collimation was provided by a lead cylinder surrounding the INTRABEAM source. Foils of high purity aluminum were placed at the exit of the collimator, and attenuation measurements were performed using a PTW 23342 parallel-plate chamber. The measured HVL was determined by curve fitting of the experimentally determined attenuation data. The statistical uncertainty in the MC-calculated HVL was determined by propagating the fluence spectrum uncertainty across the calculation of air-kerma ratio, taking into account photon cross-section uncertainty. The sources of MC systematic uncertainty considered were: the variation in polyetherimide (applicator material) density, collimator positioning error, and source-to-detector positioning error. In the experimental HVL measurement, the uncertainty was estimated by the tolerance of aluminum attenuator thicknesses and the 95% confidence interval of the fitted attenuation curve. The accuracy of the HVL determination is a critical step in the reference dose calibration of the INTRABEAM source. Our results indicate that the presence of the lead collimator, due to the emission of fluorescent x-rays, had a non-negligible effect on HVL measurement for the spherical applicators. In the MC calculation of spherical applicator HVLs, the collar positioning error was found to be one of the dominant contributions to uncertainty (ΔHVL = 0.03 mm Al). For the simulated bare probe HVL, statistical errors and source-to-detector positioning contributed equally to the overall uncertainty. Upon comprehensive analysis of sources of experimental errors, we conclude that the simulated HVLs were in good agreement with measurement for the bare probe and spherical applicators.
SP068.4 - Low Energy Therapeutic X-Ray Calibration Methods

Northwest Medical Physics Center, Lynnwood/UNITED STATES OF AMERICA

The application of low energy X-rays has recently increased in the dermatology workspace, with the generating tube potential of these radiation beams spanning from 10 to 70kV. Absolute calibration of these low energy radiation units from three different manufacturers has been conducted. Various low-energy calibration protocols were considered for calibrating the low energy beams of the X-ray tubes from three different manufacturers. These protocols included the American Association of Physicists in Medicine (AAPM) Task Group 61 Report (for 40-300 kV beams), the UK Code of Practice from the Institution of Physics and Engineering in Medicine and Biology (IPEMB) for very low-energy X-rays (8-50 kV), International Atomic Energy Agency (IAEA) Technical Reports Series No. 398 (for X-ray up to 100 kV), and Report 10 of the Netherlands Commission on Radiation Dosimetry for low energy X-ray (50-100 kV). Review and comparison of the methodology of these protocols, pertaining to the energy range of Grenz-rays to superficial X-rays, is conducted.

In general, standard calibration laboratories provide an in-air calibration factor, Nk (air-kerma in Gy), and/or an in-water calibration factor, ND,w,Qo (absorbed dose to water in Gy). These factors can in turn be used in air or in a phantom in a clinical setting. The aforementioned protocols allow one or more of such calibration conditions. Because of the wider availability of Nk calibration factors from the US-based standard calibration laboratories and ease of using an in-air calibration technique for low-energy X-ray beams in a clinical setting, the AAPM-TG61 protocol and the data extracted from the British Journal of Radiology Supplement No. 25 were found to be the most practical for the calibration of low energy X-ray units for dermatological applications.

The issues with calibrating such low energies radiation units include having the appropriate equipment, creating a precise physical setup for measurements, and the low SNR when performing HVL measurements. The HVL setup needs to be stable and precise, due to the sensitive nature of these measurements. An air gap between the chamber and the source at these low energy units can change the results significantly. For example, a one millimeter air gap between a specially designed parallel-plate chamber and one of these low-energy X-ray producing units can cause an error in the order of 3%.

SP068.5 - Energy response of a thimble-type ionization chamber for Ir-192 and Co-60 radiation beams

Author(s): Cecilia Kessler, David Burns
BIPM, Sèvres/FRANCE

A new international comparison for primary determinations of reference air-kerma rate using Ir-192 brachytherapy sources has been established by the Bureau International des Poids et Mesures (BIPM) and registered in the BIPM Key Comparison Data Base (KCDB) as an ongoing key comparison under the reference BIPM. Rli(K)-K7.

The participants in this key comparison, the National Metrology Institutes NMs, calibrate a thimble-type ionization chamber, model NE 2571, under reference conditions following the corresponding protocol. The comparison result, and thus the degree of equivalence between the NMI and the BIPM, is based on the ratio of the NMI calibration coefficient to that of the BIPM, the latter chosen as the Key Comparison Reference Value (KCRV).

As the BIPM has no primary facility for Ir-192 brachytherapy sources, the reference value is evaluated from the calibration coefficient of the ionization chamber determined in the BIPM reference Co-60 beam, with a correction factor kN applied to account for the energy dependence of this type of chamber.

This correction factor is calculated using the Monte Carlo code Penelope [1]. The simulation of the chamber (dimensions, shape and materials) was made using the geometry code Pengeon, based on the manufacturer data sheet for the chamber. Using this code, a typical Ir-192 source used for therapy with its encapsulation was simulated.

In the first step the user code simulates the energy spectrum of the Ir-192 source and creates a phase-space file at 5 cm from the source reference point, recording the energy, spatial coordinates and direction of each particle. This file is used in the second step as an input to calculate the calibration coefficient of the ionization chamber at 1 m from the source.

Similarly, the calibration coefficient of the ionization chamber is evaluated for the Co-60 beam, using as input the existing phase-space file corresponding to the BIPM reference beam.

The correction factor kN for the NE 2571 ionization chamber is determined as the ratio of the calibration coefficient evaluated for Ir-192 to that for Co-60. Supporting calculations are made to estimate the uncertainty of kN. The results are compared with published work.

SP068.6 - Kilo-voltage X-Ray tube dosimetry Correction factors for in-water measurement in TG-61

Author(s): Nima Sherafati1, David W.O. Rogers2
1Physics, Carleton Laboratory for Radiotherapy Physics, Carleton University, Ottawa/ON/CANADA, 2Physics, Carleton Laboratory for Radiotherapy Physics, Carleton University, Ottawa/CANADA

For x-ray tube potentials > 100 kV, the AAPM TG-61 protocol for 40-300 kV x-ray beam dosimetry in radiotherapy recommends an in-water measurement which is based on ionization chambers calibrated in air in terms of air kerma. We studied the variation of the overall correction factor (PQch) and its components (known as corrections for the change in the chamber response due to the change in the spectrum distribution in phantom compared to that used for the calibration in air (kQ), displacement of water by the ionization chamber (Pdis) and displacement of water by the stem (Psheath)) as well as the correction for a waterproofing sleeve (Psheath) with depth and field size for 6 different beam qualities in the orthovoltage x-ray range (100 kV < tube potential < 300 kV). Based on TG-61, the absorbed dose to water at the reference depth (2 cm) is given by: Dwater = Mair Nk PQch Psheath ([μν]water/air) water, where PQch is the calibration coefficient of the ionization chamber determined in the BIPM reference Co-60 beam, with a correction factor kN for the NE 2571 ionization chamber.

As the BIPM has no primary facility for Ir-192 brachytherapy sources, the reference value is evaluated from the calibration coefficient of the ionization chamber determined in the BIPM reference Co-60 beam, with a correction factor kN applied to account for the energy dependence of this type of chamber.

This correction factor is calculated using the Monte Carlo code Penelope [1]. The simulation of the chamber (dimensions, shape and materials) was made using the geometry code Pengeon, based on the manufacturer data sheet for the chamber. Using this code, a typical Ir-192 source used for therapy with its encapsulation was simulated.

In the first step the user code simulates the energy spectrum of the Ir-192 source and creates a phase-space file at 5 cm from the source reference point, recording the energy, spatial coordinates and direction of each particle. This file is used in the second step as an input to calculate the calibration coefficient of the ionization chamber at 1 m from the source.

Similarly, the calibration coefficient of the ionization chamber is evaluated for the Co-60 beam, using as input the existing phase-space file corresponding to the BIPM reference beam.

The correction factor kN for the NE 2571 ionization chamber is determined as the ratio of the calibration coefficient evaluated for Ir-192 to that for Co-60. Supporting calculations are made to estimate the uncertainty of kN. The results are compared with published work.

factor is insignificant. The new values agree well with TG-61 values which demonstrates that the systematic uncertainties in EGS4 cancelled out since the factors are all ratios. Due primarily to its high-z electrode, the variation of PQch with depth and field size for the Exradin A16 ionization chamber is up to 10 percent and the variation with beam quality is up to 40 percent. This suggests ionization chambers with high-z electrodes should not be used for x-ray dosimetry. Depth and field size dependance of the PQch for the Exradin W1 scintillator detector are also being studied.

SP069 - Novel Detectors, Phantoms and Software, Diagnostic Techniques

SP069.1 - Synergistic Action of Ionizing Radiation with Platinum-based Chemotherapeutic Drugs: Soft X-rays and Low-Energy Electrons

Author(s): Elahe Alizadeh¹, Mohammad Rezaee², Darel Hunting³, Leon Sanche³

¹Department Of Chemistry And Biochemistry, University of Guelph, Guelph/CANADA, ²Princess Margaret Cancer Centre, Department Of Radiation Oncology, University of Toronto, Toronto/CANADA-DA, ³Département De Médecine Nucléaire Et Radiobiologie, Faculté De Médecine Et Des Sciences De La Santé, Université de Sherbrooke, Sherbrooke/QC/CANADA

The biological impact of ionizing radiation results predominantly from the induction of a variety of lesions in cellular DNA via energy deposition into the DNA itself (direct effect) and its surrounding molecular environment (indirect effect) [1]. The most numerous of intermediate species arising from the direct effect of radiation are non-thermal secondary electrons [2], most of which having energies below 30 eV (i.e., low-energy electrons, LEEs). In the present study, we report results to evaluate the direct effect of ionizing radiation on the formation of both single and cluster lesions in a supercoiled plasmid DNA covalently modified by the platinum anticancer drugs (Pt-drugs) cisplatin, carboplatin and oxaliplatin. Since these Pt-drugs sensitize malignant cells to ionizing radiation, they are currently used in concomittant chemoradiotherapy for cancer treatment; however, the specific mechanisms of the interaction between these Pt-drugs bound to DNA and radiation still remain to be determined [3,4].

Freeze-dried nanoscale films (~10 nm) of either pure DNA or a Pt-drug covalently bound to DNA were prepared onto two different types of substrates, i.e., tantalum and glass surfaces. Samples were exposed to 1.5 keV X-rays, in the presence of dry nitrogen gas and no humidity [5]. The yields of single- and double-strand breaks (SSBs and DSBs) and interduplex cross links (CL) induced in both types of films by X-rays and the spectrum of photo-electrons emitted from tantalum were determined from the initial linear slopes of respective exposure-response curves. In addition, the ratios of the yields from the two different films were determined and referred as an enhancement factor (EF) to represent radiosensitization by the Pt-drugs.

Results presented in Table 1 clearly show that Pt-drugs substantially enhance the formation of DSB and CL in DNA irradiated by X-rays and LEEs, but have virtually no effect on SSB formation. Furthermore, the EFs for DSB and CL are larger for LEEs than X-rays in the presence of Pt-drugs. Since LEEs constitute a major portion of the secondary species generated by high-energy radiation, our finding suggests that in the presence of Pt-adducts, LEEs are the main secondary species responsible for the increase of DSB and CL in the irradiated platinated DNA via the direct effect. According to the linearity of the exposure-response curves, these damages result from a single-event process. Despite similarity between Pt-drugs in the enhancement of the DNA lesions, carboplatin and then oxaliplatin have higher efficiency than cisplatin in the radiosensitization of DNA.
Current electron beam dosimeters face two major challenges. They are not water/tissue equivalent, and therefore require conversion to dose to water/tissue. Moreover, they must be placed in the radiation beam, which results in beam perturbation and dose averaging. These challenges limit their spatial resolution for intensity-modulated delivery or *in vivo* dosimetry. Yet, Cherenkov radiation by high-energy charged particles is emitted in water and in tissue, can be detected outside the beam, and is inherent to all high-energy radiotherapy beams. Despite these advantages, Cherenkov dosimetry has yet to be implemented for clinical dosimetry. The work presented here investigates via first-principles derivation and Monte Carlo simulation the feasibility of absolute Cherenkov dosimetry for electron beam radiotherapy. A quantitative model for predicting absolute dose from Cherenkov intensity in a phantom was derived from first principles for high-energy charged particles of known incident energy with the assumption that all collisional energy loss is absorbed and all radiative energy loss escapes. The model was validated via simulation of 260 keV - 18 MeV electrons incident on water. Monte Carlo simulations were carried out in Geant4. The absolute Cherenkov dosimetry model presented here was able to predict absolute dose from Cherenkov intensity to within a clinically viable uncertainty of less than 3%.

**SP069.3 - Detection of melanoma through image recognition and artificial neural networks**

**Author(s):** Cristofer I. Marín1, Germán H. Alférez1, Jency Córdova2, Verenice González2

1Global Software Lab, Universidad de Montemorelos, Montemorelos Nuevo León/MEXICO, 2Departamento De Apoyo A La Investigación De Ciencias En Salud, Universidad de Montemorelos, Montemorelos,Nuevo León/MEXICO

The incidence of malignant melanoma has significantly increased in the last four decades. Dermatologists are rarely present in rural or remote areas to perform an early detection of malignant melanoma. Our contribution is a low cost software that automatically and objectively differentiates between a melanoma lesion and a benign nævus in a simple, noninvasive manner. Our approach is based on the “ABCDE” classification of lesions, image processing, and artificial neural networks. The software was developed using images of previously diagnosed malignant melanomas and non-malignant suspicious moles, obtaining a sensibility of 76.56% and a specificity of 87.58%.

**SP069.4 - Clinical Implementation of an Intraoperative Radiotherapy Program**

**Author(s):** Muthana Al-Ghazi1, Varun Sehgal1, Dante Roa1, Suhong Yu2, Qichao He2, Jeffrey Kuo2, Erin Lin2, Alice Police2

1Radiation Oncology, University of California, Irvine, Orange/UNITED STATES OF AMERICA, 2Surgery, University of California, Irvine, Orange/CA/UNITED STATES OF AMERICA

**Purpose:** To outline the process for setting up an intraoperative radiotherapy (IORT) program and its clinical implementation, including dosimetric data, radiation safety aspects and clinical procedures.

**Background:** IORT has been used in the past for clinical indications such as in the management of localized abdominal tumors. Where applicable, it is efficient and convenient as the radiation treatment is completed at the time of surgery. The modality was almost abandoned except for select large institutions due to the high cost incurred in installing dedicated linear accelerators and orthovoltage units and the requirement for extensive shielding of specially designed operating rooms.

Advances in design of miniaturized x-ray tubes operating at 50 KVP initiated resurgence of interest in this modality. The Zeiss system (Zeiss Inc., Jena, Germany) consists of a portable 50 KVP x-ray tube that is mounted on a robotic arm with 6 degrees of freedom. A sterile applicator is mounted on it and the latter is placed at the tumor bed for dose delivery. Accuracy of applicator position is verified using ultrasound image guidance. A 1 mm sterile tungsten (W) shield is wrapped around the applicator. The shield reduces the radiation levels in the room by a factor of 103. The procedure can be safely performed in a regular operating room.

**Methods:** The dosimetric characteristics of the system are confirmed using a parallel plate chamber connected to an electrometer. Measurements are made in a specially designed water phantom. Clinical dose calculations are carried out using these parameters. A check list is developed for quality assurance and safety measures consistent with institutional requirements and manufacturer’s recommendations for safe and accurate delivery of radiation treatment following accepted treatment protocols.

Importantly, a radiation survey is carried out around the operating room where IORT procedures take place to ascertain safe levels of exposure to personnel who are not classified as radiation workers. This is easily achieved using the W shield alluded to above.

**Results:** Dose delivery to patients undergoing IORT using the procedure outlined above can be carried out safely in a regular operating room. The exposure levels in adjacent areas are comparable to background. The procedure is cost effective due to the portability of the system and the low energy of the x-ray emission. Clinically, the system has been used to treat localized early breast tumors and abdominal sites. Detailed dosimetric, radiation safety and clinical data pertaining to the program will be presented.

**Conclusion:** An IORT program has been implemented at the University of California, Irvine Medical Center for the treatment of breast and abdominal tumors. The approach is convenient to patients as it delivers the radiation treatment at the time of surgery. This is espe-
Conclusion:
A new back-etched silicon detector array has been developed and characterised. Initial testing of the array integrated into a real-time microbeam monitoring system, shows very promising results.

SP069.6 - Dynamic Mechanical Characterization of a Poly(vinyl alcohol) Breast Palpation Phantom

Author(s): Gabriel A. Rodriguez
Carnegie Mellon University, Pittsburgh/UNITED STATES OF AMERICA

Breast phantoms model quantitative and qualitative parameters of bulk tissues to provide a foundation for the calibration and design iteration of different imaging methodologies, particularly for breast cancer screening. Existing breast phantoms can accurately emulate specific properties of tissues for conventional imaging modalities such as MRIs or ultrasound, but are inadequate for the large deformations associated with mechanical palpation. Polyvinyl alcohol (PVA) cryogels provide a unique solution because of stability at large deformations, although current cryogel processing methods suffer from inhomogeneity for large structures such as tissue phantoms. Established cryogel fabrication protocols tune the specific mechanical properties of PVA cryogels by varying concentration of PVA in the solution and the number of freeze-thaw cycles that the cryogel undergoes. Chaotropic salt inclusions in PVA promote amorphous behavior in the cryogels, resulting in an increase in the homogeneity to the bulk mechanical properties of the phantom. This study evaluates the effects of varied salt concentrations on the dynamic mechanical properties of cryogels to improve the stability of mechanical breast tissue phantoms. The elastic and viscoelastic properties of conventional cryogels are compared to cryogels with salt inclusions using dynamic loading. To characterize the tissue analogs for clinical utility, the experimental protocol uses simple compression, large deformations, and strain rates equivalent to those used in clinical palpation. Results are compared with literature values for both fatty and fibroglandular breast tissues. By improving the homogeneity of PVA cryogels with the use of salt inclusions, this work builds on existing tissue analog technologies. Further development of mechanically-accurate and multi-modal breast phantoms will provide low-cost and safe alternatives to clinical trials for the validation of developing breast imaging technologies.
SP070 - Molecular Imaging PET/SPECT: Part 2

SP070.1 - Optimal Pixelated Crystal for a Molecular SPECT Scanner: A GATE Monte Carlo Study
Author(s): Mohammad Reza Ay1, Hojat Mahani2, Gholamreza Raisalii2, Alireza Kamali Asl3
1Department Of Medical Physics & Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN, 2Radiation Application Research School, Nuclear Science and Technology Research Institute, Tehran/IRAN,3Shahid Beheshti University, Medical Radiation Faculty, Tehran/IRAN

Objective: It is well-known that resolution-sensitivity tradeoff is the most challenging design consideration in small-animal SPECT. In the present work, we addressed such a compromise from pixelated crystal point-of-view for HiReSPECT system, a high-resolution SPECT camera, developed at Research Center for Molecular and Cellular Imaging.

Materials and Methods: For this purpose, we performed GATE Monte Carlo package to simulate the HiReSPECT scanner and to assess the impact of various crystal configurations on tomographic resolution and system sensitivity, using a 99mTc point-like source and a flood-field phantom, respectively. The crystals differed in material, pixel-size, and Epoxy pixel-gap. Point-spread-functions (PSFs) were iteratively reconstructed using a dedicated 3D OSEM algorithm. Equal importance factors were assigned to the two conflicting objectives, and pixelated crystal was then optimized using the weighted-sum method. In addition, the Monte Carlo simulations were validated by means of comparisons with the experimental data.

Results: A good agreement (4.3% difference) between simulated and measured tomographic spatial resolutions at 30 mm radius-of-rotation is observed. Likewise, there is a maximum 9.1% difference, at 120 mm source-to-collimator distance, between our Monte Carlo calculations and the experiments for system sensitivity, all for a 1 × 1 mm² pixel-size and 0.2 mm Epoxy gap CsI(Na) configuration. The results show that CsI(Na) exhibits the highest sensitivity compared to NaI(Tl) and YAP(Ce) as well as a slightly higher spatial resolution, and therefore is the crystal of choice. A sensitivity of 1.61 cps/μCi is achieved for a 1.5 × 1.5 mm² pixel-size and 0.1 mm Epoxy gap CsI(Na)-based camera. Changing pixel-size from 0.5 × 0.5 mm² to 2 × 2 mm² leads to a 35.7% loss in tomographic resolution while sensitivity improves by a factor of 1.52. Based on our Monte Carlo optimization, the 1.5 × 1.5 mm² pixel-size and 0.1 mm Epoxy gap CsI(Na) is the optimal configuration by providing the best tradeoff between spatial resolution and system sensitivity. The crystal-optimized HiReSPECT system also offers a tomographic resolution of 2.98 mm, in terms of FWHM.

Conclusion: Our findings highlighted that performance of a preclinical SPECT imaging can be highly affected by the pixelated scintillator configuration, and therefore searching for an optimum configuration is mandatory in order to obtain a more qualified SPECT image.

SP070.2 - Spinning Knife-Edge Slit-Hole: a Novel Collimation for High-Sensitivity Molecular SPECT
Author(s): Hojat Mahani1, Gholamreza Raisali2, Alireza Kamali Asl2, Mohammad Reza Ay1
1Research Center For Molecular And Cellular Imaging, Tehran University of Medical Sciences, Tehran/IRAN, 2Radiation Application Research School, Nuclear Science and Technology Research Institute, Tehran/IRAN,3Radiation Medicine Engineering Department, Shahid Beheshti University, Tehran/IRAN

Objective: While conventional collimation systems are widely used in molecular SPECT, such collimators usually limit performance of the camera due to owing a low geometric efficiency. In the present study, we addressed this challenge by proposing a novel collimator offering a high-sensitivity HiReSPECT system, a high-resolution SPECT camera, developed at Research Center for Molecular and Cellular Imaging.

Materials and Methods: For this purpose, we performed GATE Monte Carlo toolkit to design and simulate the collimator for the HiReSPECT scanner. The prototype consists a centered single camera’s head, with 30 mm collimator’s depth. Planar spatial resolution and in-air sensitivity were assessed at various distances using a 99mTc point-like source and a flood-field phantom, respectively. At each regular SPECT angle, 16 spin-projections over 180° were then acquired each with 3.75 s time-per-spin. The planar images were iteratively reconstructed using a dedicated MLEM-based algorithm. To speed up our Monte Carlo simulations, a variance reduction technique by ignoring transport of the secondary electrons was also implemented.

Results: Slit-hole geometry give rise to an increased background-subtracted sensitivity of 12.4 times that observed with parallel-hole collimator at 30 mm source-to-collimator distance. System sensitivity with slit-hole collimator falls off as filed-of-view of the camera increases and reaches to a value of 4.6 cps/μCi at 120 nm distance while sensitivity of the system with parallel-hole collimation remains approximately constant over all distances from the collimator and has a value of 1.32 cps/μCi. Slit-hole collimated HiReSPECT scanner provides a magnification factor of 3 and offers a planar spatial resolution, in terms of FWHM, of 3.32 mm compared to 2.91 mm obtained by a parallel-hole collimation, at 10 mm source-to-collimator distance. Implementation of the variance reduction technique in our Monte Carlo simulations results in a 1.51 acceleration factor while imposes no significant effect on spin-projection data.

Conclusion: Our preliminary findings highlighted that the spinning
slit-hole is a promising alternative for parallel-hole collimators with acceptable planar spatial resolution, and therefore the proposed collimator provides a better resolution-sensitivity tradeoff.

Comparison of system sensitivity for the parallel-hole and the slit-hole collimated HiReSPECT scanner. For the slit-hole collimation, the sensitivity is background-subtracted.

SP070.3 - Simultaneous estimation of the radioactivity distribution and electron density map from scattered coincidences in PET: A project overview  
**Author(s):** Honovan Sun, Mohammadreza Teimoorisichani, Bryan McIntosh, Geng Zhang, Harry Ingleby, Andrew Goertzen, Stephen Pistorius  
**Affiliation:** 1Physics And Astronomy, University of Manitoba, Winnipeg/CANADA, 2Radiology, University of Manitoba, Winnipeg/MB/CANADA

Quantitatively accurate PET images require correction of measured data for scattered coincidences. Additionally, an anatomical image is required to provide accurate attenuation correction and to facilitate the interpretation of the activity distribution. By taking advantage of accurately measured photon energies and the kinematics of Compton scattering, a 2D surface described by two circular arcs (TCA), which define the possible scattering loci and encompasses the annihilation position, can be identified. In 3D the annihilation is confined to the volume encompassed by the surface obtained by rotating the 2D arc around its axis. Using this premise, we have developed novel iterative reconstruction algorithms which use the scattered coincidences to 1) improve the activity distribution and 2) obtain an electron density map. The results have demonstrated the feasibility and benefits of incorporating scattered coincidences into the image reconstruction process. Incorporating scattered coincidences directly into the radiotracer reconstruction algorithm eliminates the need for scatter correction, and could improve both image quality and system sensitivity. The electron density map reconstructed from scattered coincidences can be directly applied to attenuation correction of the activity distribution, which removes energy scaling and registration problems.

**Introduction:** It is well known that prostate imaging is one of the killer applications of PET/MRI systems. The main challenge of the current PET/MRI systems in this region field is inaccurate attenuation map (µmap), due to the fact the attenuation coefficients of the tissues are considered as soft tissue or fat in the generated µmaps. This issue leads to overestimation of the tracer uptake in the air cavities of rectum and bowel as well as underestimation of the tracer uptake in bone and adjacent areas to bone in the corrected PET images, especially in regions with thick cortical bones. The aim of this study is to increase the number of tissue classes of µmap in the pelvic area from one class or two classes in currently available PET/MRI scanners to four classes, namely cortical bone, air, soft tissue and fat, by means of a full automatic method. The proposed method consists of a combination of imaging technique, along with an image segmentation protocol.

**Material and Methods:** The proposed imaging technique was STE (short echo time) that set on a clinical 1.5T scanner in the pelvic area of two volunteer. The acquisition parameters were 1.31 ms and 60 ms for TE and TR, respectively, with Ernst angle of 15°. The image processing protocol includes five major steps as follows: (I) intensity-inhomogeneity correction; (II) separation of cortical bone and air from other regions using a region-base level set method; (III) separation of cortical bone and air areas using shape analysis method, based on morphological characteristic including level of circularity and symmetry; (IV) separation of soft tissue and fat using thresholding and (V) generation of µmap. The validation of the proposed method was based on comparison with the µmaps generated by CT images as gold standard.

**Results:** Figure 1, shows acceptable performance the proposed method in segmentation and generation four-class µmap. Quantitative analysis on dice and sensitivity factor are 71% and 65% respectively in cortical bone segmentation as well as 78% and 76% in air segmentation and 82%, 93% respectively, for fat segmentation.

Fig 1. MR image(rowA); segmented image(rowB); µmap(rowC)

**Discussion:** The proposed strategy in this study showed that the four-class µ-map can be successfully generated from only one STE-MR image in order to save time, following by the proposed six steps protocol. The proposed method can be a potential alternative to Ultra short echo time (UTE) MR-based attenuation correction, particularly in more common hybrid PET/MRI systems.
SP070.5 - Extracting PET activity distribution from scattered coincidences for non-ideal energy resolutions by modeling the probabilities of annihilation positions within a generalized scattering reconstruction algorithm

**Author(s):** Hongyan Sun¹, Stephen Pistorius²  
¹Physics And Astronomy, University of Manitoba, Winnipeg/MB/CANADA, ²Radiology, University of Manitoba, Winnipeg/MB/CANADA

Scattered coincidences degrade PET images contrast and compromise quantitative accuracy, and corrections for this are required in conventional PET reconstruction algorithms. In contrast to this approach, we have developed an algorithm that extracts the radioactivity distribution by incorporating scattered coincidences into the reconstruction. Using the kinematics of Compton scattering, two circular arcs (TCA), as shown in Fig.1(a), describe the locus of all possible scattering positions and encompass the annihilation position for a scattered coincidence. PET images can be reconstructed from scattered coincidences by projection and backprojection within the area confined by the TCA if the detectors have perfect energy resolution. In our previous work, the varying probability of the annihilation position within TCA is not modeled and a uniform distribution is assumed. In practice, the estimated annihilation position is sensitive to the energy resolution of the detector, which limits the implementation of the proposed algorithm on existing clinical PET scanners. In this work, the probability map of annihilation positions within the TCA is modeled in a normalized coordinate system (See Fig. 1(b)). This map was blurred in the vertical direction to account for the non-ideal energy resolution of the system (see Fig.1(c)), and was incorporated into the generalized scattered (GS) reconstruction algorithm. The results demonstrated that by modeling the probabilities of the annihilation position within the TCA in a normalized coordinate system and by introducing this probability map into the reconstruction, the convergence of the reconstructed activity distribution is improved. The contrast for images generated from scattered events improved by 7% compared to those that did not include the probability distribution in the reconstruction (see Fig.2). For non-ideal energy resolutions of up to 6%, the proposed method improves the contrast and noise properties of the reconstruction.

SP070.6 - Quantitative Functional Imaging with Hybrid PET-CT Via Improved Kinetics Modeling: Application to 18F-Fluorochocline PET Imaging of Prostate Cancer

**Author(s):** Adam Blais, Mark Dekaban, Jennifer Hadway, Ting Yim Lee  
Lawson Health Research Institute, London/ON/CANADA

**Motivation:** ¹²⁴F-Fluorocholine (FCH) PET imaging is of interest for the localization of prostate cancer and has the potential to allow more accurate targeting for both biopsy and intra-prostatic radiation dose escalation. However, studies using the standardized uptake value (SUV) have been unable to differentiate prostate cancer from benign prostatic hyperplasia. We hypothesize that this is due to the confounding effects of blood flow and blood volume in the local vasculature, which cannot be discriminated using the SUV. Quantitative kinetic analysis of FCH PET can account for this confounding effect by estimating the k₃ parameter, which represents the activity of the choline kinase enzyme, but this is difficult because high parameter covariance reduces the robustness of the k₃ estimate.

**Methods:** We developed a hybrid DCE-CT/PET kinetic model, which uses DCE-CT functional maps to reduce the effect of parameter covariance. Furthermore, this linearized model form is solved with a non-negative least squares algorithm which has only one possible solution and is computationally efficient. Simulations were conducted to investigate the accuracy and precision of k₃ estimates and an FCH PET imaging study of a PC-3 mouse model was analyzed to show proof of concept.
Cancers are highly hypoxic, and (iii) there is no significant correlation between perfusion and hypoxia in our cohort of patients.

**Conclusions:** In summary, we have developed a computationally efficient technique for accurate estimation of $k_3$ from noisy dynamic PET data that may be capable of differentiating malignant prostate cancer from benign tissue.

**SP070.7 - Simultaneous Measurement of Perfusion and Hypoxia in Pancreatic Cancers with Dynamic PET-FAZA Imaging**

**Author(s):** Ivan Yeung¹, Cristiane Metran-Nascente², Doug Vines¹, Ur Metser¹, Neesha Dhani², David Green¹, Michael Milosevic¹, David Jaffray¹, David Hedley²

¹Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/CANADA, ²Medical Oncology, Princess Margaret Cancer Centre, Toronto/CANADA, ³Medical Imaging, Princess Margaret Cancer Centre, Toronto/CANADA

**Background:** Pancreatic cancers are believed to be poorly perfusion and hypoxic, and these characteristics have been suggested to explain in part their aggressive biology and poor response to standard treatment. **Method:** We have developed a method to quantify perfusion and hypoxia in pancreatic cancers with dynamic PET imaging post injection of $^{18}$F-fluoroazomycin arabinoside (FAZA). A cohort of 20 patients with pancreatic cancers were scanned with the scanning protocol involving dynamic PET acquisition in the first 60 min followed by a single static scan at 2 hr. The dynamic data were binned for image reconstruction with intervals starting from 10s up to 5 min whereas the static scan was scanned with 2 bed positions of 15 min each. The images were viewed and tumor contoured by a radiologist. To quantify the perfusion component of the tracer kinetics of FAZA, the dynamic data (of 19 patients) were analyzed with a two-compartment model with which, ‘Ktran’ was calculated as a surrogate of perfusion. Repeated analyses were done on data over 1.5, 5.5 and 15 min to investigate the length of data required to estimate Ktran. The static images were analyzed with the ‘Mortensen’s method’ for hypoxic fraction. The method determines, for each patient, the tumor to mean muscle (skeletal muscle) uptake ratio for each voxel in the tumor; those voxels with uptake ratio higher than unity plus 3 times the standard deviation of the population normalized muscle uptake will be classified as ‘hypoxic’. The percentage of ‘hypoxic’ voxel within the whole tumor will give ‘hypoxic fraction’. The method determines, for each patient, the tumor to mean muscle (skeletal muscle) uptake ratio for each voxel in the tumor; those voxels with uptake ratio higher than unity plus 3 times the standard deviation of the population normalized muscle uptake will be classified as ‘hypoxic’. The percentage of ‘hypoxic’ voxel within the whole tumor will give ‘hypoxic fraction’. **Results:** Ktran estimates of 1.5 min data are found to be poorly correlated ($r=0.60$, 0.62) based on the Pearson correlation test with those of 5.5 min and 15 min, whereas the ktran estimates of the latter two are found to be highly correlated ($r=0.98$). The mean Ktran of 5.5 min data is $0.384±0.108$ ml/min/g and the hypoxic fraction ranges from 0.0 to 57.6% with median hypoxic fraction of 2.2%. The Pearson correlation between Ktran values and hypoxic fractions gives a negligible slope of $-0.001$ and $r=0.0016$ as shown in the figure. **Conclusions:** The preliminary results suggested that (i) data of 5.5 min are sufficient to provide robust estimates of Ktran, (ii) The preliminary results do not support the notion that pancreatic cancers are highly hypoxic, and (iii) there is no significant correlation between perfusion and hypoxia in our cohort of patients.

Photo-polymerizable hydrogels have been widely researched as tissue engineering matrices. When designing a new photo-crosslinkable, biosynthetic hydrogel system, a number of parameters need to be optimized, such as the polymerization conditions and amount of biological polymer included. This study aimed to investigate the crosslinking parameters (i.e., choice of initiator, light intensity and irradiation time), as well as the biological polymer (i.e., gelatin) content, for a degradable tyramine functionalized poly(vinyl alcohol) (PVA-Tyr) system. This PVA-Tyr can be photocrosslinked using a visible light initiated process composed of ruthenium (Ru) and persulfate compounds. Comparison of ammonium persulfate (APS) and sodium persulfate (SPS) showed that SPS supported fabrication of higher quality gels at lower concentrations than APS. The initiator concentration and irradiation conditions that were found to produce the best quality PVA-Tyr gels were 2 mM Ru/20 mM SPS and 3 minutes of 15 mW/cm² of visible light. Moreover, incorporation of gelatin into the PVA-Tyr gels successfully facilitated attachment of Schwann cells on the gels. The Schwann cells were able to survive and proliferate over 3 days on the PVA-Tyr/gelatin gels. Overall, this study showed that PVA-Tyr gels have high potential as biomaterials for tissue engineering applications.

SP071.2 - A synchrotron radiation microtomography study of wettability and swelling of nanocomposite Alginate/Hydroxyapatite scaffolds for bone tissue engineering

Author(s): Francesco Brun1, Gianluca Turco2, Sergio Paolotti3, Agostino P. Accardo4
1Department Of Engineering And Architecture, University Of Trieste, Trieste/italy
2Department Of Medicine, Surgery And Health Sciences, University Of Trieste, Trieste/italy
3Department Of Life Sciences, University Of Trieste, Trieste/italy

Wettability and swelling properties play an important role in a tissue engineering scaffold. An effective methodology for the characterization of these aspects is here presented and applied to nanocomposite Alginate/Hydroxyapatite scaffolds for bone tissue engineering. The methodology exploits synchrotron radiation computed microtomography and image analysis. Wet conditions with both water and simulated body fluid (SBF) were applied to the synthesized 3D constructs and the structure alterations were investigated after 21 days and 60 days of embedding. A quantitative analysis of wettability and swelling behavior through time is also presented and discussed.

SP071.3 - ECM production and distribution in regenerated cartilage tissue cultured under traction loading.

Author(s): Keisuke Fukuda1, Seiji Omata2, Yoshihiro Sawae3

2Research Center For Advanced Biomechanics, Kyushu University, Fukuoka/Japan
3Faculty Of Engineering, Kyushu University, Fukuoka/Japan

An arthrodial cartilage covers sliding surfaces of a diarthrodial joint, and it has important mechanical functions, such as impact absorption, friction reduction, etc. Mechanical stresses and strains exerted in articular cartilage during daily joint movements can stimulate the metabolism of chondrocytes. For the cells embedded in the cartilage, they play an important role to sustain the health and homeostasis of the cartilage tissue. Especially, upregulative effects of the cyclic compression and the hydrostatic pressure on the chondrocytes biosynthesis of extracellular matrix (ECM) have been studied extensively and utilized in the cartilage tissue engineering. However, the regenerated cartilage does not have sufficient dynamic functionalities compared with the normal arthrodial cartilage. The load which arises in a living body is not the simple in fact. The chondrocyte would be exposed to the dynamic and complicated strain field consisting of compression, tension and shear that exerted by both joint loading and friction at the cartilage surface. In this study, the relative motion between cartilage surfaces in a synovial joint is simulated by the rolling-sliding motion of the plastic roller on the cultured chondrocyte-agarose construct and its effects on the formation of regenerated cartilage tissue was investigated.

Chondrocytes isolated from cartilage tissues harvested from metacarpal-phalangeal joints of steers were seeded in agarose gel and cultured 2 or 3 weeks with a traction loading applied to the surface by a roller in the original traction loading machine. This machine consists of upper oscillating plastic roller and lower reciprocating specimen stage. Vertical movement and oscillation of the roller and horizontal reciprocation of the stage were independently driven by three AC servomotors, which were controlled by PC through a control board. The specimen fitted into the culture dish was mounted on the stage and the roller was rolled over its upper surface with a defined slip/roll ratio to apply the traction loading to the construct.

After the culture period, we evaluated the amount of Type II collagen and Glicosaminoglycan (GAG) and also observed the distribution on these ECM molecules in the construct. To identify effects of the traction loading, a control specimen with a same initial cell density and same dimensions was also prepared and cultured simultaneously under the free swelling condition. After the culture experiment, constructs cultured under the traction loading had a clear traction track on the upper surface. Therefore, samples for the analyses were divided into three groups, traction track, outside of the traction track and free swelling condition.

The experiment showed that the traction loading applied to the surface of chondrocyte-agarose constructs could not increase the amount of ECM molecules accumulated in the regenerated cartilage tissue. But, it brought the anisotropic nature in the elaborated cartilaginous tissue and ECM rich layer was formed in the articulating surface of the construct cultured under the traction loading. Therefore, the traction loading on the surface may have a/potential to make the structural anisotropy like a natural articular cartilage in regenerated cartilage tissue.
SP071.4 - Alginate encapsulation: a solution for controlled infiltration of cells within artificial fiber constructs

Author(s): Oleksandr Gryshkov, Holger Zernetsch, Nicola S. Hofmann, Birgit Glemmacher
Leibniz University Hannover, Institute for Multiphase Processes, Hannover/GERMANY

Introduction

Tissue-engineered constructs containing living cells are promising in the field of regenerative medicine and cell-based therapies. The application of tissue engineering presents an engineered polymeric-cell construct as an attractive option to treat cardiovascular disorders. A seeded scaffold faces the problem of the growth of cells only on the surface. On the other hand, by combining the encapsulation of cells within alginate beads with scaffold structures, one can develop 3D scaffolds with encapsulated cells [1]. The advantage of this approach, in contrast to direct cell seeding, is in the potential of alginate beads to protect encapsulated cells from shear stress, which occur upon seeding and culture.

Methods

The developed high voltage method was utilized to encapsulate NIH 3T3 cells in 1.5% sterile-filtered alginate solution at concentration of 3x106 cells/ml. After encapsulation alginate beads were washed twice with washing solution (WS, 10 mM HEPES, 1.5 mM CaCl2 at pH = 7.4). Polycaprolactone/polyactic acid fiber mats (PCL-PLA) were generated using electro-spinning. The embedding of alginate beads into PCL scaffold was performed manually at sterile conditions. Afterwards, PCL-PLA fiber mats with entrapped alginate beads containing 3T3 cells were washed twice with WS and cultured in a humidified incubator at 37°C, 5% CO2 for 24 days. Medium was exchanged every second day with a fresh one. The membrane integrity of 3T3 prior to encapsulation and after dissolution of alginate structure was analyzed using Trypan Blue exclusion method. The viability of encapsulated cells in alginate beads immediately after encapsulation and their presence within the scaffold was assessed using CalceinAM/EthD-1 live-dead viability assay. The presence of embedded alginate beads into fiber mats was confirmed using a scanning electron microscope.

Results

NIH 3T3 cells can be encapsulated into alginate beads (diameter 300 μm) using high-voltage electro-spraying without significant effect of high voltage on the viability of encapsulated cells post-encapsulation (immediate viability 92% vs. initial 95%). In turn, electro-spinning process allowed generating multi-layered PCL-PLA scaffold with previously incorporated alginate beads containing living cells. Analysis of SEM images proved the presence of alginate beads in the scaffold. Long-term culture of these constructs for 24 days revealed the simultaneous degradation of alginate beads, release of encapsulated 3T3 cells and their attachment to PCL-PLA fiber mat within the scaffold. On the other side, no viable and adherent cells were observed, if the alginate structure was treated with sodium citrate prior to long-term culture.

Conclusions and outlook

This work shows the perspectives of applying the high-voltage process to generate cell-containing tissue-engineered constructs for regenerative medicine, cell-based therapies and cardio-vascular applications. Further work will be performed to optimize the seeding process including its automatization, as well as to investigate the behavior of such constructs at dynamic conditions.

Acknowledgments

This work is in part supported by the German Research Foundation (DFG) through a scholarship of the cluster of excellence REBIRTH (EXC 62/1).

SP071.5 - Biomineralization and In vivo-Compatibility of LnPO4 Nanorods with Enhanced MR and Luminescence Imaging

Author(s): Zhongbing Huang
Sichuan University, Chengdu/CHINA

Introduction: The biocompatibility of nanomaterials with dual-functionalities is very important for their clinical applications.

Methods: Eu-doped LnPO4 nanorods (NRs) in the template of silk fibroin (SF) peptides, including GdPO4, SmPO4 (named as SF-NRs), are successfully synthesized via a biomineralization process.

Results: lengths of Eu-doped GdPO4 and SmPO4 NRs with SF peptides (SF-NRs) are ~150 and 250 nm, respectively, and their diameter is ~10 nm. Compared to pure NRs, SF-NRs have stronger cell luminescence and higher T1 signal-enhancement of in vitro/in vivo MRI due to their higher ratio of Eu/Gd (~0.9/5) or Eu/Sm (~1.3) and more Eu⁺/Eu³⁺ in SF-NRs. The images of cell ultrathin sections indicate that endocytosis of SF-NRs into the cytoplasm did not influence mitochondrial architecture at the NR concentrations of 100 mg·mL⁻¹ after 3 d of culture, because PBS/calf serum immersion tests indicate that SF peptide coating could slow metal-ions release and the crystal degradation from NRs. The histological analysis and bio-distributions in tumor-bearing nude mice suggest that, compared to pure NRs, SF-NRs have lower tissue/organ toxicities and could be safely cleared away through renal and fecal excretion in 3 days, especially the existence of more SF-NRs in the tumor field due to SF coating layer in NR surfaces. Furthermore, Eu-doped SF-NRs not only exhibit a higher T1 signal-enhancements (the longitudinal relaxation r₁ value is 1.32 (Gd mM·s⁻¹) and 0.0145 (Sm mM·s⁻¹) under a 7.0 T MR imaging system, and a series of in vivo T1-weighted MR images between pre- and post-injection in tumor regions in 9 h indicate that average intensity of post-injection of SF-NRs is enhanced 71%, higher the increased value of pure NRs (15.5%), but also show the better luminescence imaging of living cells under the fluorescence microscope.

Conclusions: Our results indicate that Eu-doped SF-NRs have potential as T1 MR imaging contrast agents and optical imaging probe in tumor-detection field.

SP071.6 - Additive Manufacturing for Creating Multifunctional Tissue Engineering Scaffolds

Author(s): Min Wang
Department Of Mechanical Engineering, The University of Hong Kong, Hong Kong/HONG KONG

Tissue engineering has great potential in solving many medical problems that are currently unsolvable or in offering better and long-term solutions as compared to current medical treatments. For human body tissue regeneration, different approaches can be adopted: cell-based, factor-based or scaffold-based tissue engineering. In scaffold-based tissue engineering, cells are encapsulated in the matrices or seeded on the surface of 3D scaffolds, with the scaffolds serving as the extracellular matrix to direct cell adhesion, proliferation and differentiation and thus promote tissue
regeneration. Over the past two decades, many materials and scaffold manufacturing techniques have been investigated by numerous groups around the world for regenerating different body tissues. So far, materials for tissue engineering are predominantly biodegradable polymeric materials, natural or synthetic, and scaffolds are produced using either non-designed manufacturing techniques (solute casting/particulate leaching, phase separation, gas foaming, electrospinning, etc.) or designed manufacturing techniques. Using designed manufacturing techniques, which include a host of additive manufacturing technologies (the so-called “rapid prototyping (RP) technologies” in previous decades), for making tissue engineering scaffolds has distinctive advantages over some commonly used chemical engineering methods in scaffold fabrication and hence has been attracting increasing attention in the biomedical field. Some additive manufacturing technologies impose stringent requirements for stock materials and studies are thus conducted on preparing stock materials and on evaluating the physical and mechanical properties of scaffolds made of these stock materials. Realizing the shortcomings of common biodegradable polymers as materials for tissue engineering scaffolds with regard to some specific tissues, various research groups now investigate new, more appropriate materials for the regeneration of targeted tissues, which include biodegradable ceramics (including glasses), composites and even metals. Considering the extracellular matrix of bone is a natural nanocomposite comprising nano-sized apatite and collagen fibrils, it is natural to develop polymer-based nanocomposites containing nanoparticles of bioactive and biodegradable ceramics as novel scaffold materials for bone tissue regeneration. Furthermore, mesenchymal stem cells (MSC) are increasingly used in tissue engineering. In this presentation, for illustrating developing biomedical nanocomposites and using additive manufacturing to form multifunctional scaffolds, our research in employing selective laser sintering (SLS), a well-established additive manufacturing technology, for obtaining osteoconductive and osteoinductive scaffolds for bone tissue engineering is introduced. Microspheres of nanocomposites (CHA/PLLA or Ca-P/PHBV) are firstly prepared as raw materials for SLS. Scaffold models of required features can be designed using computer-based medical imaging techniques (e.g., MRI). That established with two different dosage. The third dosage with the same ions and energy need to be tested.

Hypothesis:

Ion beam implantation onto random oriented fibrous scaffold produced by the electrospinning will promote radial artery cells adhesion, migration, differentiation and proliferation. This is the first step towards the successful tissue engineering.

Materials and Methods:

In this study, Collage Rat tail –Type-1 is the material in used to fabricate the electrospinning fibers. These electrospun collagen fibers are crosslinked using a physical approach via ion implantation. Broad energy He⁺ (Helium) and N⁺ (Nitrogen) ion beams are used. Energies of 1.7 MeV and 520 MeV of N⁺ ion and He⁺ ion, respectively were used to surface modify the collagen nanofibrous scaffold. The dose of these ions with similar energies, where varied from (4*10¹⁵ ions/cm² - 1.2* 10¹⁶ ions/cm²)

Results

These cross-linked scaffolds (nanofibrous) displayed stability in both water and cell culture media with controllable degrees of swelling, where established with two different dosage. The third dosage with the same ions and energy need to be tested.

Discussion and summary

So far, with one of the energy of 1.7 MeV N⁺ of dose of 1.2 * 10¹⁶ ions/cm² and 520 MeV He⁺ of dose of 8 *10¹⁵ ions/cm² at room temperature. The X-ray photoelectron spectroscopy (XPS) shows that with nitrogen implantation, two new chemical functional groups, amine and amide, are introduced, which could promote cell adhesion. And, these functional groups were not found in He⁺ implantation.

Introduction:

Engineering methods to construct biological tissue substituted has been inspired due to the shortage of donor organ transplantation. Where, the scaffold plays an important role as of assisting, an artificial extracellular matrix to accommodate cells and support three-dimensional tissue regeneration. An ideal scaffold should be biocompatible, biodegradable, malleable, mechanically strong, and highly porous with a large surface to the volume ratio. Such, ideal scaffolds are highly in demand, for surgical application, regenerative medicine, cell based therapy. An electrospun nanofibrous collagen scaffold is desirable for tissue engineering application, but as prepared, it is unstable in an aqueous environment including cell culture media. Stabilization of these nanofibers has been achieved to varying degrees of success using a chemical crosslinking approach with crosslinking agent such as glutaraldehyde, but they are cytotoxic.

SP072 - Imaging

SP072.1 - Variations in geometric distortion using static and moving table acquisition for radiotherapy treatment planning applications

**Authors:** Amy Walker¹, Gary Liney¹, Lois Holloway², Jason Dowling³, David Rivest-Henault³, Peter Metcalfe² ¹Medical Physics, Liverpool and Macarthur Cancer Therapy Centres and Ingham Institute for Applied Medical Research, Liverpool/ AUSTRALIA, ²Centre For Medical Radiation Physics, University of Wollongong, Wollongong/AUSTRALIA, ³Commonwealth Scientific And Industrial Research Organisation, Australian E-Health Research Centre, Brisbane/QLD/AUSTRALIA

**Purpose:**
Geometric accuracy is essential when imaging patients for radiotherapy treatment planning (RTP). An increased use of MRI for RTP requires consideration of inherent geometric distortions. This study compared variations in geometric distortions observed during image acquisition utilising a continuously moving table, compared to a conventional static table. Continuous moving table acquisition allows for imaging of a longer scan length than static acquisition, a potential benefit for RTP.

**Methods:**
A new full field of view (FOV) phantom for measuring MRI geometric distortion for the purposes of RTP was designed in-house. Constructed from Dotmar Uniboard, 5830 vitamin E capsules were placed systematically throughout. Phantom dimensions were 500mm x 350mm x 513mm (x,y,z respectively). The phantom was scanned on a Siemens 3 T Skyra with a spoiled gradient echo (GRE) sequence (vendor 3D-correction applied). The phantom was imaged with a static couch and a continuously moving table (TimCT). The MR images were registered to a CT of the phantom to obtain distortion maps.

**Results:**
Table 1 compares the geometric performance of images acquired with and without a moving table. TimCT enabled imaging of the whole phantom. TimCT acquired with a table speed of 1.1mm/s resulted in the best geometric accuracy. However, the acquisition time was over 9 minutes compared to 2 minutes for the static acquisition. Increasing the table speed to 2mm/s decreased acquisition time, but resulted in increased blurring of the capsules by 170% at the FOV edges. TimCT was limited to 2 possible imaging sequences.

**Conclusions:**
MRI acquisition utilising TimCT offers a potential alternative for imaging large scan lengths which may be required for RTP, particularly for long FOVs. Both static and moving table image acquisitions are viable scanning options for imaging for RTP. Selection of the acquisition method would depend on the anatomical region under investigation.

SP072.2 - Translation of biomechanical deformable image registration (MORFEUS) to the RayStation radiotherapy treatment planning system

**Authors:** Michael Velie³, Joanne L. Moeley¹, Stina Svensson², Björn Hårdemark¹, Kristy K. Brock³, David Jaffray¹ ¹Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/ON/CANADA, ²RaySearch Laboratories, Stockholm/SWEDEN, ³University of Michigan, Ann Arbor/MI/UNITED STATES OF AMERICA

**Purpose:**
Deformable image registration accuracy can vary widely between imaging modalities and even implementations of similar deformation models. Biomechanical model-based deformable registration was implemented in a commercial radiotherapy system and validated on multi-modality imaging.

**Materials and Methods:**
MORFEUS is a MATLAB-based registration algorithm previously developed and validated in-house. A multi-organ tetrahedral mesh model is generated from contours in the reference image, while a subset of additional surfaces is created from body, liver and spleen contours in the target image. These three organs undergo individual surface deformations to align the contours between images and serve as boundary conditions. Finite element analysis (FEA) solves the internal displacements including all of the remaining organs and tumors. Under research collaboration with RaySearch Laboratories, MORFEUS was implemented in a commercial radiotherapy treatment planning system. Results shown are from a pre-clinical release of RayStation (v4.4.100). The organ-specific material properties were optimized separately between implementations. The Poisson’s ratios applied in-house (range: 0.4-0.499) differ by <10% from those applied in RayStation-MORFEUS. Variable Young’s moduli are applied in-house (range: 1.5–500 kPa), whereas RayStation-MORFEUS effectively applies a uniform stiffness. Boundary conditions are achieved using guided-surface projections for the in-house MORFEUS, whereas RayStation-MORFEUS uses model-based segmentation which adapts a common mesh to corresponding contours. Different third party components are also used for mesh generation and FEA solver, although these function similarly. For 32 patients in total, registration of abdominal images was performed from exhale to inhale 4DCT (or MR), or exhale CT to MR. One patient with 4DCT and MR was previously evaluated in a multi-institution accuracy study, allowing for a comparison to other algorithms. For evaluation between deformed and actual target images, the target registration error (TRE) was quantified as the residual distance between anatomic liver landmarks (median: 5, range: 4-25). For 4DCT and MR-MR, the residual mean distances of the stomach and kidneys surfaces (organs excluded as boundary conditions) were additionally quantified.

**Results:**
The Table demonstrates the registration accuracies of both MORFEUS implementations differ by <1 mm, and both accuracies
are similar to each image resolutions on average. In the multi-institution comparison, for 4DCT both MORFEUS implementations’ TRE were within 1 mm of the best-performing algorithm. For CT-MR, the in-house and RayStation-MORFEUS TRE was 1.0 and 1.2 mm lower than the best-performing, non-biomechanical algorithm.

*p≤0.05 versus RayStation-Morfeus

Conclusions: MORFEUS biomechanical registration was implemented in RayStation. Its registration accuracy and difference from the original implementation are on average within the voxel sizes on multi-modality abdominal imaging.

SP072.3 - Phantom Validation of a Point-Set Deformable Registration Method using Pig Bladder

**Author(s):** Roja Zakariae1, Ghassan Hamarneh2, Colin J. Brown2, Ingrid Spadinger3

1Physics, University of British Columbia, Vancouver/BC/CANADA, 2Medical Image Analysis Lab, School Of Computing Science, Simon Fraser University, Burnaby/BC/CANADA, 3Medical Physics, BC Cancer Agency, Vancouver/BC/CANADA

**Introduction**

Deformable image registration (DIR) is widely used for registering medical images. While the main goal of registering images is to correspond different regions of interest (ROI) within the body, surrounding objects and image artefacts can confuse the DIR algorithm. This occurs, for example, in image-guided multi-fraction gynecological brachytherapy treatment, which uses an intracavitary applicator. Therefore, in applications like dose accumulation for these treatments, an alternative approach is to non-rigidly register delineated ROI contours. However, validating the registration outcomes and accordingly choosing a suitable registration algorithm is challenging, especially for highly deformable ROI with no discriminating features or anatomical landmarks. In this work, a point-set deformable registration technique, called coherent point drift (CPD), is evaluated for registering the bladder surface across treatment fractions.

**Methods**

A house-made pelvis phantom was used with a freshly harvested pig bladder to model the human anatomy. Multiple plastic and rubber fiducial markers were glued onto the bladder surface at twelve different locations. The bladder was filled with varying amounts (90cc, 180cc, 360cc, and 480 cc) of a water-contrast mixture and CT-scanned each time. The variously filled bladder was contoured manually on each scan using the MIM Maestro software (MIM Software Inc.). In addition, the fiducials were identified on each scan and their positions recorded. The CPD toolbox for MATLAB (Mathworks Inc.) was used to register the contour point-sets of the three smaller bladder sizes to the largest size. The toolbox takes the target and moving structure coordinates and outputs the de-
formed moving structure coordinates. The fiducial positions were used as landmarks to calculate the target registration errors (TRE) for different points on the bladder surface. Optimized input parameters for CPD registration were found experimentally by searching over the parameter space for values which minimized average TRE over all landmarks.

Results

The appearance of the phantom and the fiducial markers in the CT images was very satisfactory (Fig. 1). The average TRE value obtained for the 480cc-bladder as the target structure was 6.4±2.3 mm. TRE values were obtained for alternate target structures, with the 360cc-bladder yielding the lowest TRE value of 5.5±2.1 mm when selected as the target. These TRE values are reasonably small compared to the dimensions of the bladder.

Conclusion

Our validation method shows that the CPD deformable registration technique is a viable method for registering ROI contours, even when lacking distinctive features in the structure.

SP072.4 - Automatic bone and air segmentation during generation of synthetic CT from MR data in the brain

Author(s): Joshua Kim, Weili Zheng, Indrin J. Chetty, Carri Glide-Hurst

Radiation Oncology, Henry Ford Health System, Detroit/MI/UNITED STATES OF AMERICA

Adequate differentiation of short-T2 tissue types such as bone from air remains a significant challenge for generating accurate electron density maps. This work describes the integration of ultra-short echo time (UTE) datasets and derivative images into our automated brain synthetic CT (synCT) pipeline to generate synCTs for our MR-only radiation treatment planning (RTP) workflow. MR Data from five brain cancer patients were acquired using Philips’ 1.0T Panorama open MR-SIM. T1-weighted fast field echo, T2-weighted turbo spin echo, FLAIR, and UTE-DIXON (TE = 0.144/3.4/6.9ms) sequences were acquired for all patients. Affine registrations to the UTE magnitude image (UTE1) were performed. A “bone-enhanced” image was generated from DIXON-water, DIXON-fat, and inverted UTE1 datasets. Images were integrated into an automatic routine using k-means clustering with five clusters and morphological operations to segment combined bone and air voxels. A novel method incorporating post-processed UTE phase maps was introduced, enabling automated segmentation of air voxels from bone via a six-kernel Gaussian Mixture Model. A truth table was constructed based on voxel intensity levels in acquired T1, T2, and FLAIR images to assign non-bone/non-air voxels to three classes: CSF, brain tissue, and fat. A voxel-based weighted summation method incorporating T2, FLAIR, UTE1, and “bone-enhanced” images was implemented with synCT voxel values calculated by:

$$\text{synCT}_i = \sum \text{wk}_i \text{r}(i) \text{M}_k$$

where M_k is intensity for voxel i of MR image k, r(i) is the voxel’s assigned class, and wk(i) is a class-dependent weighting factor optimized by minimizing the sum of squares error between simulation CT (simCT) and synCT using a training subset. HU value differences were compared using mean absolute error (MAE). Figure 1 illustrates simCT and synCT images for two patients. Average full-field-of-view MAE over all patients was 164.8±23.4 HU, showing close agreement with expected values. UTE phase-derived air maps were compared to threshold-derived simCT air contours, overlapping with 87.2±6.1% of simCT-based volumes. However, phase-derived air maps were often larger than simCT air contours, leading to higher average HU values for simCT versus synCT in air (-695±66 HU vs. -1024 HU). Another consequence was that the enlarged phase-derived contours yielded lower average values in bone (761±86 HU vs. 841±75 HU). Automatic air and bone segmentation methodology was incorporated into a brain cancer synCT pipeline. Calculated HU values demonstrated good agreement with expected simCT values based on MAE, however further refinement of air masks using the phase-based approach is needed.

Supported in part by Philips HealthCare, Best, Netherlands.

SP072.5 - Effect of Deformable Registration Accuracy on Lung Dose Accumulation

Author(s): Navid Samavati1, Michael Velec2, Kristy K. Brock3

1Ibbme, University of Toronto, Toronto/CANADA, 2Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/CANADA, 3University of Michigan, Ann Arbor/MI/UNITED STATES OF AMERICA

Objective/Purpose: Deformable image registration (DIR) plays an important role in dose accumulation, such as incorporating breathing motion into the accumulation of the delivered dose based on daily CBCT images. However, it is not yet well understood how the uncertainties associated with DIR methods affect the dose calculations and resulting clinical metrics.

Methods and Materials: In the current study, a biomechanical model based DIR method and a biomechanical-intensity-based hybrid method, which reduced the average registration error by 1.6 mm, were applied to 10 lung cancer patients. Clinically relevant dose parameters were calculated for three dose accumulation scenarios using both algorithms. Dose scenarios included: static, predicted, and accumulated. Static dose refers to the clinical plan on the exhale phase of the 4DCT, which accounts for the breathing motion through the use of an asymmetric Planning Target Volume (PTV) margin, but does not account for the normal tissue motion in and out of the PTV during breathing motion. The predicted dose calculates the delivered dose based on the breathing motion observed on the 4DCT obtained at the time of treatment planning. The accumulated dose calculates the dose delivered based on the
4D CBCT obtained at the start of each treatment fraction. For each dose scenario, the relationship between the dose parameters and a combination of DIR accuracy (Target Registration Error, TRE, and Dice Similarity Coefficient, DSC), tumor volume, and dose heterogeneity of the plan was investigated.

Results: Depending on the dose heterogeneity, measured by Dose Heterogeneity Index (DHI), tumor volume, and DIR accuracy (measured by DSC), in over 30% of the cases differences greater than 1.0 Gy were observed in the minimum dose to 0.5cc (Dmin) of the tumor in the static dose calculation. Such differences were due to the errors in propagating the tumor contours from the reference planning 4D CBCT phase onto a subsequent 4D CBCT phase using each DIR algorithms and calculating the dose on that phase. The differences were more subtle when breathing motion was modeled explicitly (predicted dose) with only one case with over 1.0 Gy Dmin difference. Dmin Differences of up to 2.5 Gy were found in the total accumulated dose due to inter-fraction variations. Such dose uncertainties could potentially become clinically significant. Thus, clinical implications of DIR-based dose accumulation outcomes should be interpreted in the context of the geometric uncertainties associated with the DIR algorithm. More specifically, our results suggest that one might expect larger than 1 Gy differences in a specific Dmin (static, predicted, or accumulated) due to DIR choice in 10-60% of a patient population if two or more of the following criteria are met: 1) DHI of the plan is larger than 20, 2) DIR induced DSC differences in the tumor exceeds 0.08, and 3) tumor volume (or tumor volume difference) is larger than 10 cc (or 5%).

Conclusion: In summary, reductions in average uncertainty in DIR algorithms by 1.6 mm may have a clinically significant impact on the decision-making metrics used in dose planning and dose accumulation assessment.

SP072.6 - Development of a Multi-Modality 4D biomechanical Phantom for Evaluation of Simultaneous Registration/Segmentation Algorithms
Author(s): Daniel Markevich, John Larkin, Pierre Leger, Ives R. Levesque, Issam El Naqa
1Medical Physics Unit, McGill University, Montreal/Canada, 2Medical Physics, Montreal University Health Centre, Montreal/Canada, 2Oncology, Montreal University Health Centre, Montreal/QC/Canada, 2Research Institute of the McGill University Health Centre, Montreal/QC/Canada

Purpose: Simultaneous registration and segmentation, known as segmentation, has the potential to improve both accuracy and efficiency of both procedures when using multimodal images or longitudinally acquired scans. Currently, no gold standard exists for the evaluation of registration algorithms, in contrast to existing segmentation or registration algorithms, where several systems have been developed. Presented is a phantom and software package that satisfies several criteria: PET/CT/MRI compatibility, realistic geometric deformations, and reliable ground truths for both segmentation and registration, sequential or simultaneous, with a high degree of consistency.

Method and Materials: The phantom consists of a pair of inflatable swine lungs connected to an in-house built programmable respirator (shown in figure 1) via an 8 meter long vinyl tube. This allows metallic components to stay outside the scan room and thus ensure MRI compatibility. The respirator is able to mimic the breathing traces of patients taken using respiratory bellows. The target was constructed in two compartments from vacuum-sealed sea sponges. The inner and outer compartments simulate a tumor and background respectively. Catheters lead into each compartment allowing for injection of radioisotopes. The registration ground truth is determined using a bifurcation-tracking pipeline. The accuracy of the tracking pipeline was evaluated by applying a known virtual deformation to a CT volume of the swine lungs and comparing the known final locations to the ones detected by the pipeline. The segmentation ground truth was acquired by scanning the corresponding BV dataset separately and rigidly registering it to the original scan.

Results: The average bifurcation tracking error was found to be 1.22, 1.26 and 2.26 voxel widths for displacement magnitudes of 2.6, 5.2 and 7.8 cm respectively using a CT scan of a human lung. The tracking error was similarly measured to be 1.36, 1.63 and 2.46 voxel widths for displacements of 1.14, 2.29 and 3.43 cm using the swine lungs. The respirator was able to match breathing traces with a maximum error of 2.2% and an average error of 0.5%.

Conclusion: The 4D biomechanical lung phantom has shown to be a reliable tool for evaluating segmentation algorithms. The bifurcation-tracking pipeline’s accuracy was measured on the order of a single voxel width up to an acceptable displacement. This is crucial in eliminating the unknown uncertainty with which manual selection of fiducial points may introduce into the evaluation of a registration algorithm.

Fig. 1 The computer controlled respirator with its 4 cm range of motion shown.

SP072.7 - Using Magnetic Resonance Image (MRI) alone in Treatment Planning and Treatment Localization
Author(s): Shupeng Chen, An Qin, Di Yan, Hong Quan
1Radiation Oncology, Beaumont Health System, Royal Oak/MI/UNITED STATES OF AMERICA, 2School Of Physics And Technology, Wuhan University, Wuhan/CHINA

Purpose: Using MR image directly for dose calculation and patient treatment position localization has been expected. In this study, a method of creating a virtual CT image from a MR image was proposed and evaluated using the corresponding CT image numbers, planning dose distribution, and accuracy of daily CBCT image registration.

Method: A pair of MR image and CT image was collected in same day from each of 10 prostate cancer patients. For each patient, the pair of MR and CT images was pre-registered using the deformable image registration (DIR). Then the corresponding CT images were deformed toward MR to create a CT-MR pair. ROIs on the pair of images, including bone, prostate, bladder, rectum and skin, were delineated and used to create ROI masks. ’Leave-one-out’ test (9 atlas patients, 1 tested patient) was performed. For each test MR image, auto-segmentation and deformable vector field (DFV) were generated based on inter-patient DIR between the test MR image and the 9 atlas MR images. Synthetic CT was then generated using the paired CT and the corresponding DFV (MR, MR) in the atlas.
The voxel intensity in the synthetic CT was determined based on the paired CT images and the corresponding masks based on the intersection of the masks. The evaluation included the comparison of the CT number, the corresponding calculated dose distribution and the corresponding registration to daily CBCT images between the resulting synthetic CT and the paired CT.

**Result:** The mean ± STD of CT number error that calculated on 10 synthetic CT are (2.4 ± 25.23), (-1.18 ± 39.49), (-32.46 ± 81.9) and (8.07 ± 146.94) for prostate, bladder, rectum and bone, respectively. The dose discrepancy calculated using the synthetic CT and the actual CT is small, difference of D99 and D95 of target were < 1%, D40 and D5 of rectum and D50 of bladder were < 1.05%. Using the 10 synthetic CT as the reference planning CT for patient daily CBCT (364 fractions) localization achieved the similar results compared to using the actual CT. The translational vector difference were within 1mm with mean ± STD (0.37 ± 0.23mm), and the rotational discrepancy was within 1 degree in all 3 directions.

**Conclusions:** Synthetic CT created using the atlas of pre-registered CT and MR image pairs can be used to be the planning and localization CT image for dose calculation and daily patient position localization and correction.

**SP073 - Robotics and Virtual Reality in Surgery**

**SP073.1 - Augmented Reality in Image-guided Cardiac Interventions.**

Author(s):

Many inter-cardiac interventions are performed either via open-heart surgery, or using minimally invasive approaches, where instrumentation is introduced into the cardiac chambers via the vascular system or heart wall. While many of the latter procedures are often employed under x-ray guidance, for some of these, x-ray imaging is not appropriate, and ultrasound is the preferred intra-operative imaging modality.

Two such procedures involves the repair of a mitral-valve leaflet, and the replacement of aortic valves. Both employ instruments introduced into the heart via the apex of the heart. For the mitral procedure, the standard of care for this procedure employs a 3D Trans-esophageal echo (TEE) probe as guidance. In spite of the clinical success of this procedure, many problems are encountered during the navigation of the instrument to the site of the therapy. To overcome these difficulties, we have developed a guidance platform that tracks the US probe and instrument, and augments the US images with virtual elements representing the instrument and target, to optimize the navigation process. Results of using this approach on animal studies have demonstrated increased performance in multiple metrics, and a large reduction in the number of times an instrument intruded into potentially unsafe zones in the heart.

The same platform can be employed to guide Aortic valve replacements. Conventionally, aortic valves are replaced, either using an open procedure, or under X-ray fluoroscopy guidance. The former inflicts unnecessary trauma to the patient, while the latter suffers from the problem of high radiations dose, poor target visibility and potential kidney damage as a result of x-ray contrast administration. To overcome these limitations, we have adapted the above platform to achieve an ultrasound-only solution, again augmented with virtual models of instruments and key targets to guide aortic valve replacement procedures. Preliminary results of this approach on cardiac phantoms indicate that this approach may be as effective as the standard fluoroscopy-guided technique, but without the need for radiation and contrast agents.

**SP073.2 - Assistant Laparoscopic Postural: Kinematic Behavior**

**Author(s):** Daniel Lorias-Espinoza, Arturo Minor Martinez

Bioelectronics Section, Electrical Department, CINVESTAV, MEXICO DF/MEXICO

A human laparoscopic assistant can help or hinder the work of the surgeon, so communication between the two must be natural and not cause any cooperation conflict in which the visual or motor perception of the human laparoscopic assistant hampers the optimal vision and concentration of the surgeon. This article shows a new Assistant laparoscopic called PMASS (Postural mechatronics assistant for laparoscopic solo surgery). The objective is to show their dynamic behavior.
SP073.3 - Workspace optimization of a surgical instrument for single port access surgery
Author(s): Bastian Blase, Sebastian Schlegel, Simon Albrecht
Department Of Electromechanical And Optical Systems, Technische Universität Berlin, Berlin/GERMANY

Instruments for laparoscopic single port access surgery have to perform specific movements inside the human abdomen to enable surgeons to perform similar tasks they are familiar with from multi-port minimally invasive surgery. Therefore, these instruments have to move apart before coming together at the surgical site to imitate an anthropomorphic position similar to standard access, thus facilitating handling at the desired target. These movements require additional joints. These joints weaken an instrument’s shaft structure and often lead to reduced strength, whereas parallel structures reduce workspace. Hence, instruments with a segmented planar hybrid parallel-serial mechanism have been developed, combining the advantages of both structures. This mechanism is coupled serially with an end-effector. Within a set of several geometric parameters and boundaries, the favored mechanism is optimized by varying the segments’ lengths for maximizing a so-called area of dexterity comprising all points that can be reached within an angular range of at least 60°. This area can be described in a cylindrical coordinate system in a phase space composed of the radial tool tip position and its inclination. The different movements of the mechanism and the end-effector are superposed and the phase space is analyzed using image evaluation methods. The optimized dexterous workspace by far exceeds a previously defined area of interest that was determined during in-vivo tests. The instruments based on this optimization proved to be agile in several tests like pick-and-place tasks.

SP073.4 - High-Dexterity Telemanipulation Robot for Minimally Invasive Surgery
Author(s): Sebastian Schlegel, Simon Albrecht, Bastian Blase
Department Of Electromechanical And Optical Systems, Technische Universität Berlin, Berlin/GERMANY

A robotic telemanipulation system for single-port laparoscopy (SPL) is presented, introducing several advantages over known systems. Principally, the system offers great flexibility at the surgical site as the instrument arms are segmented and articulate within the abdominal cavity. The instrument arms were thoroughly designed to ensure stability while maintaining a small cross-section, thus keeping patient trauma to a minimum.

Apart from the arms’ solidity, the need for strong actuators is another factor that arises due to the requirement for high manipulation forces during surgery. As, at the same time, available space is extremely limited, extensive research was conducted for finding suitable actuators. Several types of actuators as well as positions within the system were taken into account, prototypes built and tested. Also, as the need arose for some concepts, mechanisms for transporting kinetic energy from the actuators to the joints were examined.

Applying the results of this work, it was possible to build a telemanipulation system consisting of instrument arms, a support base, and a specifically designed user interface. A computer serves to calculate instrument trajectories and respective joint positions from the user input at the interface as well as to facilitate communication between the system's components.

The system exceeds previously defined goals concerning dexterity. Practical tests demonstrated the broad range of movement. At the same time, the extracorporeal components are considerably smaller than their counterparts in telemanipulators on the market, thus improving direct access to the patient during surgery. Furthermore, the complex kinematics of the instrument arms are controlled via an interface with simplified kinematics modelling the instrument’s degrees of freedom (DOF), resulting in intuitive and precise handling.

SP073.5 - Integrated Sensors for a Single-Incision Laparoscopic Instrument
Author(s): Simon Albrecht, Bastian Blase, Sebastian Schlegel
Department Of Electromechanical And Optical Systems, Technische Universität Berlin, Berlin/GERMANY

This paper describes different sensor types for integration into a minimally invasive instrument for laparoscopic robotic surgery. A bionic fiber sensor helps to avoid collisions between the instruments’ arms and the abdomen during manipulation. Position measurement is included by means of magnetic sensors that deliver feedback signals for the drive mechanism. To provide the surgeon with a haptic feedback, two force sensors are studied to be incorporated into a single incision laparoscopic robotic instrument. Their individual characteristics and impact on haptic feedback are investigated, taking into account the individual sensors’ locations.

SP073.6 - Development and Evaluation of an Open-Source 3D Virtual Simulator with Integrated Motion-Tracking as a Teaching Tool for Pedicle Screw Insertion
Author(s): Stewart Mclachlin, Brendan Polley, Mirza Beig, Jeremie Larouche, Cari Whyne
Sunnybrook Research Institute, Toronto/Canada

Pedicle screw insertion techniques are traditionally taught with limited hands-on training, using artificial or cadaveric models, prior to guided supervision within the operating room. As residency programs move to competency-based curricula, more authentic and accessible teaching tools are required to train next generation spine surgeons. Virtual simulation can provide a valuable tool for practicing challenging surgical procedures; however, its potential depends on effective integration into student learning. The objectives of this work were to develop a freely accessible virtual pedicle screw simulator and to improve the clinical authenticity of the simulator through integration of low-cost motion tracking.

The open-source medical imaging and visualization software, 3D Slicer, was used as the development platform for the virtual simulation. 3D Slicer contains many features for quickly rendering and transforming 3D models of the bony spine anatomy from patient-specific CT scans. The virtual simulation needed to include both pre-operative planning and intra-operative pedicle screw
insertion workflows. Pre-operative planning utilizes CT imaging to identify the vertebral levels requiring instrumentation and take anatomic measurements. The intra-operative screw insertion workflow requires identification of the correct entry point and trajectory to create a safe screw tract with a pedicle probe. This requires skill in complex 3D spatial perception and interpreting 2D images into real-world 3D positioning. To address this required skill development, virtual monitoring of the surgeon’s simulated tool was assessed with a low-cost motion tracking sensor in real-time (~$80, LeapMotion, San Francisco). This allowed a screw surrogate to be tracked as the surgeon defined the virtual screw’s insertion point and trajectory on a 3D spine model.

Using a combination of existing and custom-written 3D Slicer Python scripts, an interactive virtual pedicle screw simulator was created. The surgical planning and operative screw insertion were simulated in a six step workflow: (1) identify vertebral levels on CT imaging, (2) choose the surgical region of interest, (3) select screw entry points, (4) take anatomic measurements, (5) define screw trajectory via the LeapMotion, and (6) grade final screw positioning. Initial surgeon feedback of the virtual simulator with integrated motion tracking was positive, with no noticeable lag and high accuracy between the real-world and virtual environments. The software yields high fidelity 3D visualization of the complex geometry and the tracking enabled coordination of motion to small changes in both translational and angular positioning.

The 3D Slicer-based virtual pedicle screw simulation overcomes accessibility issues of previously developed simulators by allowing distribution without the need for expensive commercial software. This will enable trainees to practice instrumentation techniques anywhere they have access to a computer. Further the interactivity provided by the low-cost LeapMotion represents a significant advancement in terms of the simulator’s task authenticity. Future work will evaluate the benefit of this simulation platform with use over the course of resident spine rotations to improve planning and surgical competency and in quantitatively evaluating performance.

SP073.7 - A Robotic System with Ultrasound Imaging for Patient Setup and Monitoring during Fractionated Radiotherapy

Author(s): Hasan T. Seri1, Peter Kazanzides1, Iulian Iordachita2, Muyinatu A. Lediju Bell3, Xiao Li1, Lin Su3, Yin Zhang3, Kai Ding4, John Wong3

1Department Of Computer Science, Johns Hopkins University, Baltimore/UNITED STATES OF AMERICA, 2Department Of Mechanical Engineering, Johns Hopkins University, Baltimore/UNITED STATES OF AMERICA, 3Department Of Radiation Oncology, Johns Hopkins University, Baltimore/UNITED STATES OF AMERICA

We are developing a cooperatively-controlled robot to assist with the application of ultrasound for patient setup and treatment monitoring of abdominal organs during fractionated radiotherapy. The proposed workflow introduces the robot for both simulation and treatment. During simulation, the operator places the 3D ultrasound (US) probe to visualize the target and the probe pose (position and orientation, in room coordinates) is measured by a ceiling-mounted optical tracker. The robot then holds a model probe at this pose during CT acquisition, and also records the probe contact force. The model probe has the same dimensions as the US probe but does not contain any metal parts that would cause CT artifacts. Treatment planning is performed on this CT image with probe-induced deformation. On each treatment day, the robot assists the operator to place the probe at the same pose and contact force as simulation. This cooperative control mode is enabled by a force sensor mounted between the robot end-effector and probe, which measures forces applied on the probe. Virtual springs guide the operator toward the recorded pose, but the operator can pull against the springs to override the recorded pose and replicate the US image recorded during simulation. This may be necessary to compensate for patient setup errors or anatomical changes. Once the US probe is placed to match the simulation conditions, it can provide real-time monitoring during radiation delivery.

We performed canine experiments using a custom robot that had five active degrees-of-freedom (DOF) and eight passive DOF. In these experiments, three 2.38 mm spherical metal markers were implanted into the kidney of a canine. We followed the proposed workflow for simulation and six fractionated treatments, except that we acquired additional images to measure the markers. Our results showed that placing the US probe at the same pose (in room coordinates) can result in soft-tissue setup errors of up to 35 mm, even after employing conventional setup procedures. The large inter-fraction variation is due primarily to the difficulty in repeatably repositioning the anesthetized canine. In contrast, the virtual springs enabled the operator to override this pose based on US image feedback and reduce the setup error to within 7 mm. Our experiments also revealed ergonomic challenges, especially because the robot had fewer than six active DOF. We are therefore updating the design to use a commercial 6 DOF robot (UR5, Universal Robots, Odense, Denmark), as shown in Fig. 1.
SP074 - Biomedical Monitoring and Bioelectromagnetism

SP074.1 - Towards Dual Respiratory and Cardiac Gated Radiotherapy

Author(s): Kirpal Kohli1, Feng-Yu Liu1, Kalpagam Krishnan1, Devin Schellenberg2, Ash Parameswaran2, Steven Thomas2, Anand Karvat2
1Medical Physics, BC Cancer Agency, Surrey/BC/CANADA, 2Radiation Oncology, BC Cancer Agency, Surrey/CANADA, 2Simon Fraser University, Burnaby/CANADA, 2BC Cancer Agency, Vancouver/CANADA

Gating provides a potential solution for managing organ displacement during radiation treatment. In particular, respiratory gating of radiation therapy is an evolving field of study [1,2]. Cardiac gating, meanwhile, remains a largely unexplored area of potential benefit. Electrical impedance measurement has demonstrated its potential application in gating. In the present study, the respiratory and cardiac traces of three healthy human volunteers were recorded by using bioimpedance based simultaneous respiratory and cardiac monitoring circuitry developed in our previous study [3]. Each subject was instructed to maintain a normal breathing rate and hold their breath for a fixed duration. Respiratory motion was also monitored simultaneously using the existing Real-time Position Management™ (RPM) system for validating the impedance trace based on the respiratory motion. Interference caused by the respiratory motion was observed on the recorded cardiac induced bioimpedance change. Comparison of the cardiac traces for both normal breathing and breath holding revealed that the amplitude of the cardiac trace appeared to be modulated by the respiratory pattern. For the signal traces to be potentially applicable for gating purposes, it is desirable that the rendered signal waveform has stable amplitude. The aim of the study is thus to develop a strategy for improving the usability of the cardiac induced bioimpedance trace for radiotherapy gating purposes. A strategy is developed for largely removing the interference in the cardiac signal caused by the respiratory motion based on amplitude demodulation. The following Figure 1 shows a sample bioimpedance trace of recorded respiratory and cardiac motions, together with the amplitude demodulated cardiac trace.

The present study focuses on analyzing the correlation between the cardiac induced and respiratory induced impedance changes recorded and deriving a numerical technique for reducing the fluctuation in the amplitude of the cardiac signal. The technique developed will contribute to the potential application of bioimpedance signal on gating of radiotherapy.

SP074.2 - A mobile terminal to follow-up the evolution of chronic diseases

Author(s): Hector Torres, Rene Gonzalez, Daniel Campillo, Eyglis Ledesma
Medical Equipment Development, Central Institute of Digital Research, La Habana/CUBA

This paper presents the firmware design of a low cost and consumption portable device intended to collect (Bluetooth) and transmit (GSM/GPRS) biological signals to a website. This solution forms part of an ambulatory monitoring system for patients with related heart diseases like arrhythmia, hypertension and diabetes, giving a more close interaction between patients and doctors. The hardware is based on the MSP430F5419A microcontroller, the CC2540 Bluetooth Low Energy (both from Texas Instruments), and the SIM908 GSM/GPRS/GPS modem from Simcom. The real time operating system FreeRTOS was used in the firmware. QRS complexes are detected and processed in the ECG wave signal; blood pressure and glucose level are processed as well. A robust communication protocol was implemented and an easy graphical user interface also. A total of 50 different samples were uploaded to the website using developed prototypes in a safety way. This is an interesting solution to have into account in this kind of systems due to its low cost.

SP074.3 - Relationship between the tuning characteristics of stimulus frequency otoacoustic emissions and behavioral tests at moderate levels

Author(s): Yao Wang1, Qin Gong2, Tao Zhang2
1Biomedical Engineering, School of Medicine, Tsinghua University, Beijing/CHINA, 2Tsinghua National Laboratory for Information Science and Technology (TNList), Beijing/CHINA

Frequency selectivity, the ability of the auditory system to resolve the frequency components of complex sounds, is typically estimated in humans using a subjective method, the measurement of psychophysical tuning curves (PTCs). Stimulus frequency otoacoustic emission suppression tuning curves (SFOAE STCs) potentially could assess frequency selectivity objectively. We compared PTCs and SFOAE STCs in 24 normal hearing subjects using moderate-level probes with center frequencies near 1, 2, and 4 kHz, showing that both measures of frequency selectivity are similar.

SP074.4 - An Axon Mimic for Medical Electrode Tests

Author(s): Malcolm A. Latorre1, Adrian D.C. Chan2, Karin Wårdell1
1Department Of Biomedical Engineering, Linköping University, Linköping/SWEDEN, 2Department Of Systems And Computer Engineering, Carleton University, Ottawa/CANADA

Tissue’s heterogeneity makes it ineffective as a test bench and calibration standard for biomedical electrodes. There is a need for an axon mimic that can generate a stable, repeatable, programmable, and physiological A-fiber like action potential (AP). The aim of the project is to assess an electronic A-fiber like system for its potential use as a biomedical electrode test bench.

An equivalent 40 nodes of Ranvier were mimicked using resin embedded gold wire (Ø = 20 µm). All nodes share one amplitude con-
control (A) with programmable control for inter-nodal timing (t), duration (n) and propagation rate from a microcontroller running custom software. Statistically, a 20 μm diameter A-fiber has characteristic inter-nodal spacing of 2 mm and propagation speed of about 120 m/s [1] which results in a 16 μs increment time between activation of successive nodes. LabVIEW and DAQ from National Instruments (Version 8.2, National Instruments Corp. Texas USA) are used for acquisition and control. Custom software implements a simplified behavioral model based on Hodgkin and Huxley’s equation [2] with a pulse train (P(t)) propagating along the nodes.

The system was assessed by submerging the nodes in a bath of NaCl 0.9 % solution which acts as the intervening tissue mimic for testing. Data were collected using a pair of standard ECG-electrodes (4831Q, Unomedical a/s, Birkerød, Denmark) with gel removed. The electrode pair was used in a bipolar configuration positioned above the nodes. Fifty repeated measurements (P(t)) = 5, A = 1 V) verified the stability of the system where the time at maximum amplitude was t(pk_max) = 196.4 ± 0.06 ms, maximum amplitude was V(pk_max) = 37.5 ± 1.3 μV, and noise floor was Vnoise = 0.07 ± 0.017 μV.

In conclusion, the system generated a traveling pulse, with programmable amplitudes, durations and times similar to those of a biological AP. The output is stable and repeatable, and most importantly can be coupled to bio-potential electrodes. This platform allows testing and comparisons between surface electrodes and some implantable electrode configurations, as well as general electrode verification, complete systems can also be tested and compared with this stable AP generator.

SP074.5 - Evaluation the Accuracy of Oscillometric Blood Pressure Measurement According to the AAMI SP10

Author(s): Haiyan Xiang
Institute of Aviation Medicine, Beijing/CHINA

The auscultatory method is regarded as the golden standard in non-invasive arterial blood pressure measurement. The oscillometric method are used widely in most automated blood pressure measurement instruments recently. The limitation of oscillometric method is that both the systolic and the diastolic pressure are estimated using empirical criteria. In fact, there are large variance of the amplitude ratios among population. Therefore, the estimation of the systolic and diastolic blood pressure based on oscillometric technique is not always accurate. In present study, an oscillometric method blood pressure measurement experiment system was established to acquire and analyze the blood pressure measurement data of the subjects with low, medium and high pressure. Eight-five subjects with a wide range of blood pressure were recruited. Each subject was measured three times. The experiment system acquires the cuff pressure and the oscillometric pulse. The manual auscultation measurement was performed on the same-limb simultaneously by two trained observers. The data were analyzed using self-programmed analyzing software based on Matlab. The averages of systolic and diastolic ratios are 0.50 and 0.71 respectively. Both the systolic and diastolic ratios fluctuate in a wide range, especially for the subjects with higher or lower blood pressure. Based on the golden standard, the accuracy of oscillometric method would not be generally accepted for the subjects with a wide range blood pressure.

SP074.6 - PEMF effects on chondrocyte cellularity and gene expression of the rat distal femoral metaphyseal articular cartilage.

Author(s): Fernando Sotelo-Barroso, Karla S. Vera-Delgado, Elena M. Castro-Rodríguez, Cipriana Cañadillo-Cisneros, Sergio Marqués Gamino
1Ciencias Aplicadas Al Trabajo, Universidad de Guanajuato, Leon/ MEXICO, 2Centro De Investigaciones Biomédicas, Universidad de Colima, Colima/MEXICO

In recent years, interactions between electromagnetic fields and biological systems have increasingly been studied. To date, pulsed electromagnetic fields (PEMF) have a number of well-documented physiological effects on cells and tissues; including the up regulation of gene expression of the transforming growth factor beta super family members, the increase in glycosaminoglycan levels, and anti-inflammatory actions. The purpose of the current study was to determine the effect of PEMF on the rat distal femoral joint cartilage, in terms of chondrocyte gene expression level and cellularity. Twenty female 84 days old Wistar rats, were randomly assigned into two groups: the experimental group received focused PEMF (30 mT/1 Hz/30 min/20 days) on the knee (MS). The control group (Non-MS), was managed similarly, except that PEMF stimulation was simulated. All the animals were euthanized for histological and gene expression evaluation of the knee joint tissues; 6 μm cartilage longitudinal sections were obtained from formalin fixed and paraffin embedded (FFPE) samples, then stained with a hematoxileneosine technique. The sections were analyzed in a light clear field microscope in order to quantify the number of chondrocytes per optical field. To determine the expression levels of collagen type XI alpha 2 (col11a2), (sex determining region Y)-box 6 (Sox6), aggrecan (Acan), runt-related transcription factor 2 (Runx2), and alkaline phosphatase liver/bone/kidney (Alpl), total RNA was isolated from a FFPE RNAeasy Kit. For each sample R1 was reverse transcribed using oligo dT as primer. Real time PCR reactions were performed from 50 ng of cDNA. Statistically significant differences were found in joint cartilage cellularity when MS and Non-MS were compared (101.13 ± 26.61 vs 69.66 ± 15.55 cells per optical field, respectively; p = 0.001). Collagen XI, Sox6 and Aggrecan expression levels were also different in magnetically stimulated tissues relative to control (Differences were evaluated by Student’s t-test and were considered as significant when p < 0.05). On the other hand RUNX2 and ALPL expressions showed no significant differences between groups (Student’s t test, p > 0.05). These results are evidence that in vivo PEMF stimulation increases the number of well differentiated knee joint cartilage cells in healthy young adult rats. This finding indicates an in vivo trophic effect upon cartilage joint tissue. The action mechanisms could be associated to electrical characteristics of cartilage cells and could be related to new matrix production. The low gene expression of RUNX2 and ALPL supports that the chondrocytic response to PEMF do not correspond to a hypertrophic reaction. These results highlight the possible therapeutic future of PEMF in cartilage injuries, and on its ageing.

SP074.7 - Classification of responders versus non-responders to tDCS by analyzing voltage between anode and cathode during treatment session

Author(s): Isar Nejadgholi, Travis Davidson, Crystal Blais, Francois Tremblay, Miodrag Bolic
1School Of Electrical Engineering And Computer Science, University of Ottawa, Ottawa/CANADA, 2School Of Human Kinetics, University of Ottawa, Ottawa/CANADA, 3Nuraleve Inc., Ottawa/CANADA

Transcranial direct current stimulation (tDCS) has been shown to be beneficial as a potential treatment of several disorders such as depression, addiction and chronic pain. Despite promising results reported in research, there is variability in responsiveness to tDCS among subjects. However, the source of this variability is still...
unknown. Creating a mechanism of determining non-responders (vs. responders) is a crucial step in order to either understand the physiology behind tDCS or increase the effectiveness of treatment. This work proposes a versatile method to predict whether a subject responds to tDCS by analyzing the voltage measured between anode and cathode during a tDCS session. Two groups of subjects are determined as responders and non-responders by assessing the effect of tDCS on their motor potential evoked by transcranial magnetic stimulation (TMS). Voltage measurements are modeled by a double Debye model and two relaxation times are extracted for each measurement. A quadratic classifier is trained to recognize responders and non-responders based on these relaxation times. Our classification results show that there is a significant correlation between relaxation times extracted from voltage and responsiveness to tDCS determined through motor evoked potentials. These results suggest that the relative speed of polarization processes occurring in electrodes and tissue may be associated the amount of current delivered to the brain.

SP074.8 - Matlab toolbox for bioelectric cardiac images analysis

Author(s): Juan Alberto L. Cruz, Maycon Emely F. Farias Ribeiro, Ernando S. Ferreira
Department Of Physics, State University of Feira de Santana, FEIRA DE SANTANA/BRAZIL

The heart problems are recognized by the World Health Organization as a major cause of death of human beings. Supported by the concepts of bioelectricity is now possible to better understand the functioning of this organ. In the medical physics research is a priority not to study only new equipment to detect these biosignals, but also new paradigms for processing, allowing the extract improve information of heart activity. We describe isECG (Imaging System for Electrocardiography), a new MATLAB processing toolbox, for bioelectric cardiac image analysis. Using real data (magnetic resonance images and ECG data from 123 bioelectrodes from an anonymous patient) the 3D-realistic heart/thorax geometry, surface ECG-bioelectric potential mapping on torso and myocardium surface potential images were constructed. Specialized routines are available for solution the direct and inverse bioelectric problem, and the results displayed in visualization panels (windows) on the main graphical interface. All ECG bioelectrical potentials signals, are show in new graphical window, and permit it is analysis for an individual ECG signal. Preliminary results demonstrated that isECG is a toolbox that can be used for analysis and visualization of cardiac bioelectric images, and has shown promise for future studies in Bioelectromagnetism.

SP075 - SPECIAL SESSION: Appropriate Technology in Imaging and Radiotherapy - Functionality and Safety Aspects

SP075.1 - Appropriate technology in imaging and radiotherapy - Functionality and Safety aspects

Author(s): Kin-Yin Cheung1, Adriana V. Berumen2, Miriam Mikhail Lette2, Joanna Izewska3
1IOMP, Happy Valley/HONG KONG, 2WHO, Geneva/SWITZERLAND, 3IAEA, Vienna/AUSTRIA

Every country faces resource constraints of some degree insofar as provision of healthcare services, a particularly critical problem in low-resource settings and in view of the rising trend of non-communicable diseases. 70% of cancer-related deaths occur in resource-constrained settings that request access to quality and affordable technologies. In low and middle income (LMI) countries, such medical services for underserved populations are mainly provided by governments. The IAEA/WHO Directory of Radiotherapy Centres (DIRAC) indicates major radiotherapy equipment shortages in these countries. WHO data in the World Health Statistics describe the corresponding census of diagnostic and therapeutic radiation technologies and services. Prioritizing appropriate selection, allocation, use, provision and optimization of cost-effective health technologies and human resources is therefore necessary. Important elements when formulating policy for planning and procurement of healthcare technologies must take into account high cost imaging and radiotherapy equipment, and should be based upon needs assessments and country specific criteria to include compatibility with clinical needs and burden of disease, radiological safety, standard of service and practice, affordability, sustainability, minimum operating requirements, long term functionality in LMI settings in terms of working conditions and infrastructure, and access to maintenance. International guidelines, recommendations, and reports such as produced by the IAEA and WHO can be used in support of planning radiation medicine services. One particular IAEA initiative aims to propose affordable, appropriate and suitable radiotherapy equipment packages and solutions for LMI countries through an IAEA Advisory Group on Increasing Access to Radiotherapy Technologies in Developing Countries (AGaRT), promoting increased access to diagnostic and therapeutic technologies in LMI countries by encouraging the industry to offer complete and integrated solutions that are safe, affordable, highly reliable and effective for low resource settings. WHO has been advising governments for many years in the incorporation of health technologies, including for diagnostic imaging and radiotherapy. For example, the WHO has recently embarked upon a project to list priority medical devices needed for the continuum of clinical management of six highly prevalent cancers, including radiation technologies. WHO is also conducting a Global Initiative on Radiation Safety in Health Care Settings to promote safe and appropriate use of radiation in healthcare. Ten priority actions have been identified in the “Bonn Call for Action” to improve safety and quality in the medical use of radiation for diagnosis and therapy, jointly published by the IAEA and WHO in 2014; engagement of all relevant medical sector stakeholders is warranted to support implementation. The synergies between IOMP, IAEA, WHO and others can enhance the availability of these technologies. Keeping in mind that technology planning criteria are country specific and dynamically change over time as healthcare services and technologies evolve, this joint session provides an excellent forum for global healthcare professionals and experts from international organizations to exchange ideas and experiences, and explore ways of addressing challenges faced during planning and acquisition of appropriate healthcare technologies.
SP076 - Radiobiological Modelling

SP076.1 - Radiation Pneumonitis and Low Dose Radiation Hypersensitivity

Author(s): J. James Gordon1, Karen C. Snyder1, Huailiang Zhong1, Ken Barton1, Zhen Sun1, Indrin J. Chetty1, Maritha Matuszak2, Randall K. Ten Haken1

1Radiation Oncology, Henry Ford Health System, Detroit/MI/UNITED STATES OF AMERICA, 2Radiation Oncology, University of Michigan Health System, Ann Arbor/MI/UNITED STATES OF AMERICA

Analysis of a University of Michigan (UMich) clinical trial dose-volume histogram (DVH) dataset is summarized, the goal of which was to improve radiation pneumonitis (RP) prediction. A family of dose–damage profiles featuring low-dose radiation hypersensitivity (RHS) achieved higher predictive accuracy than mean lung dose (MLD), motivating a novel RHS normal tissue complication probability (NTCP) model. Results of this model are summarized. If one makes reasonable assumptions regarding the institution-specific DVH mix, the model can reproduce published MLD – RP risk curves obtained in clinical trials at Duke University, Netherlands Cancer Institute (NKI), Washington University (WU) and the University of Milan (UMilan).

SP076.2 - Dose distribution optimization methods based on biological parameters: Impact of the objective function and reoxygenation and proliferation effects

Author(s): Arcaceli Gago Arias1, Andrés Pérez1, Beatriz Sanchez Nieto1, Juan Pardo Montero2, Christian Karger3, Ignacio Espinoza1

1Instituto De Física., Pontificia Universidad Católica de Chile, Santiago/CHILE, 2Servizo De Radiofisica E Protección Radiolóxica, Complexo Hospital Universitario de Santiago de Compostela, Santiago de Compostela/SPAIN, 3Department Of Medical Physics In Radiation Oncology, German Cancer Research Center (DKFZ), Heidelberg/GERMANY

The non-uniform response of tumors to radiation may compromise radiotherapy treatment outcome when homogeneous dose distributions are used. Responsible for this behavior are mainly the inhomogeneous distributions of oxygen and clonogenic cell density within the tumor. To approach these issues, the delivery of inhomogeneous dose distributions was long ago proposed to increase the efficiency of radiotherapy.

Dose prescription is normally addressed as an optimization problem involving an objective function, OF. Two of the most frequently used OFs aim to: i) maximize the tumor control probability, which is equivalent to minimize the tumor cells survival or ii) seek a uniform density of surviving clonogens.

The published works applying any of these two approaches were implemented using different dose redistribution techniques (sub-volume dose boosting, dose painting by numbers) to tumors with distinct radiosensitivity inhomogeneities. Furthermore, they analyzed the impact of different biological factors or employed mathematical tumors modeling these processes in different ways.

This work studies different methods of dose distribution optimization analyzing the above-mentioned OFs under a common methodology. Effects related to the dose heterogeneity allowed in the distribution and the impact of biological processes like reoxygenation and tumor cell proliferation are also studied. The response of a 2-cm-diameter hypoxic Head-and-Neck virtual tumor to radiotherapy was simulated using a previously published mathematical model [Med Phys. 2015 Jan; 42(1):30]. The model considers the following biological processes: tumor cells proliferation, neo-angiogenesis, diffusion-limited hypoxia, oxygen-dependent cell killing due to radiation, resorption of dead cells, tumor shrinkage and reoxygenation.

A dose painting by numbers approach was chosen to redistribute the dose keeping the average dose delivered to the tumor equal to 2 Gy per fraction.

The impact of the different OFs and dose heterogeneity constraints on treatment outcome was first isolated from other effects. At this stage no tumor cell proliferation was simulated and the tumor oxygenation status was considered to remain constant throughout the treatment. Dose distributions derived for fraction-by-fraction optimizations led to equal treatment outcomes for both OFs. In the dose distributions, the dose modulation was allowed to vary within a 10%, 25%, 35% and a 50% of 2 Gy per fraction. This led to a reduction of 3, 7, 8 and 10, respectively, in the number of fractions needed to achieve tumor control.

Dose distribution optimizations were then performed for a dose heterogeneity limit of 25% of 2 Gy simulating the tumor response considering all the abovementioned biological processes. The effect of changes in the tumor cell proliferation rate was studied for tumor cell doubling-times ranging from 50 to 5 days, including an accelerated repopulation regime arising after two weeks of treatment. The highest therapeutic gain from dose painting was achieved for the simulations with the highest proliferation rate (reduction of 13 fractions compared to the case using uniform dose). When accelerated repopulation is considered, the number of fractions needed to achieve tumor control was lowered from 34, for uniform dose distributions, to 23. The work shows that reoxygenation and tumor cell proliferation play an important role in the simulation of dose-painting.

SP076.3 - Healthy Tissues in The Present of Gold Nano Particles against 103Pd and 125I: Monte Carlo study

Author(s): Mohammad Vahidian, Somayeh Asadi, Mehdi Vaez-Za deh, Mahdieh Marghchouei

Physics, K.N.Toosi University of Technology, 4/IRAN

The aim of the present Monte Carlo study is to evaluate the method of variation of energy deposition in healthy tissues in the human eye which is irradiated by brachytherapy sources in comparison with the resultant dose increase in the gold nano particle – loaded choroidal melanoma. The effects of GNPs on healthy tissues are compared between 103Pd and 125I as two ophthalmic brachytherapy sources. To this end, Human eye globe was simulated through the use of MCNP5 code by considering all parts of the eye. Dose distribution in healthy tissues and dosimetry differences in the eye phantom with existing tumor have been taken into account for both mentioned brachytherapy sources. In addition deviations observed in the comparison of simple water phantom and actual simulated eye in present of GNPs are also a matter of interest that has been considered in the present work. Here, both water and eye phantoms were simulated in which the water phantom was the same as the eye phantom with the exception that, water was considered to be the eye composition in all parts of the human eye globe. The previous studies which compared the ophthalmic brachytherapy dosimetry between these two sources reported higher absorbed dose by the tumor for 103Pd versus 125I for an equivalent radiation time. However, the results of this study show that the calculated dose enhancement factor in the tumor for 103Pd is higher than that of for 125I. Also, the ratio of the absorbed dose by healthy tissues in the present of GNPs to the absorbed dose by the tumor for 103Pd is lower than that.
SP076.4 - Monte-Carlo model development for evaluation of current clinical target volume definitions for Glioblastoma using Boron Neutron Capture Therapy

**Author(s):** Leyla Moghaddasi, Eva Bezak, Wendy Harriss-Phillips
Department Of Medical Physics, Royal Adelaide Hospital, Adelaide/SA/AUSTRALIA

**Introduction:** Glioblastomas (GBM) are notorious for their extensive diffusion and high fatality rate. Boron Neutron Capture Therapy (BNCT) is a biochemically-targeted type of radiotherapy where thermal neutrons are captured by $^{10}$B, resulting in the emission of high LET α-particles and recoiling $^7$Li atoms. BNCT has the potential to selectively deliver localized dose to tumour cells diffused into normal brain tissue, with minimal normal tissue toxicity. The aim of the current work is to develop a GBM model, taking into account cellular composition of brain with addition of appropriate $^{10}$B concentrations, to determine optimal Clinical Target Volume (CTV) margins for BNCT. It also aims to investigate the effectiveness of GBM cell death (i.e. in the presence of hypoxia and genetic heterogeneity) following BNCT.

**Methods:** A neutron beam model was developed in GEANT4 9.6.p02 and verified against published data. The neutron beam spectrum was obtained from literature for a cyclotron-produced beam. The calculated percentage depth dose curves (PDDs) in water were compared with measured data to verify the neutron beam in terms of total depth dose and boron dose deposition. The GBM model was structured as follows: firstly, Microscopic Extension Probability (MEP) models were developed using MATLAB-2012a, based on clinical studies reporting on GBM clonogenic spread. Typical $^{10}$B concentrations in GBM and normal brain cells were obtained from literature. Each cell was then assigned a $^{10}$B concentration depending on its MEP status. Secondly, a Geant4 microdosimetry model was developed to calculate the dose deposited in individual voxels, each representing a GBM/normal cell; the system was defined as a cubic phantom voxelized to 20 μm side voxels (the average size of glioma cells) and irradiated with an epithermal neutron beam. The material of each voxel was set to brain tissue with addition of appropriate $^{10}$B brain tissue, with minimal normal tissue toxicity. The aim of the study was to selectively deliver localized dose to tumour cells diffused into normal brain tissue, with minimal normal tissue toxicity. The aim of the current work is to develop a GBM model, taking into account cellular composition of brain with addition of appropriate $^{10}$B concentrations, to determine optimal Clinical Target Volume (CTV) margins for BNCT. It also aims to investigate the effectiveness of GBM cell death (i.e. in the presence of hypoxia and genetic heterogeneity) following BNCT.

**Results & Conclusion:** Excellent agreement was achieved between the calculated and measured neutron beam PDDs (within 1%) (Figure 1). The resulting boron depth dose deposition was also in agreement with measured data. Ongoing work is focusing on determination of tumour cell SF following BNCT as a function of various MEP models and $^{10}$B concentrations.

**Figure 1:** Comparison of calculated and measured total PDDs of a neutron beam in water (Insert: the neutron beam spectrum).

SP076.5 - Exploring RBE Dependence on Proton Track Angular Incidence

**Author(s):** Piotr Pater$^1$, Gloria Bäckström$^1$, Fernanda Villegas-Navarro$^2$, Anders Ahnesjö$^3$, Shirin A. Enger$^1$, Jan Seuntjens$^1$, Issam El Naqa$^1$
$^1$McGill University, Montreal/CANADA, $^2$Uppsala University, Uppsala/SWEDEN

The relative biological effect (RBE) of protons, taken as the ratio of double strand break (dsb) yields for an investigated radiation source to the yields by $^{60}$Co, can be computed by overlaying event-by-event Monte Carlo (MC) particle tracks on a cell nucleus model. Strand breaks (sb) occur when energy depositions (ED) sites coincide with the DNA sugar-phosphate backbone. Dsbs are then modelled as arrangements with at least one sb on each strand within 10 base pairs (bp). Human DNA is tightly packed into higher order structures including chromosomes, chromatin fiber, and nucleosomes (beads on a string configuration). This work compares proton RBE for different angular orientations of nucleosomes relative to incident charged particle tracks within a cell nucleus model.

The MC code LionTrack (Med.Phys.2013;30(4)) was used to generate proton (~1-5 MeV) and $^{60}$Co ED tracks, including all secondary electrons (tracking cutoff of 50 eV). ED sites were subsequently overlaid on a simplified cylindrical cell nucleus (~2 μm radius and half-height) at track-nucleus angles from 0 (normal incidence) to 90 degrees (parallel to nucleus axis). Fractions of ~2 Gy were simulated at each angle for each source. A nucleosome, consisting of a 2-turn, double stranded, and circular arrangement of 99 bp pairs, is replicated in an ordered fashion approximately 3x10$^7$ times in the nucleus and dsb yields are computed for each fraction.

For $^{60}$Co, no angular dependence was detected and the 95% confidence interval on the average angular dsb yield was [2.50 2.65] dsb Gy$^{-1}$ cell$^{-1}$, which was used as the reference to calculate RBE for protons. RBE was larger than one at all proton energies and incidence angles, with two significant trends: As expected, the RBE increased with decreasing proton energy. However, RBE also significantly depends on the track-nucleus angle, due to a preferential track alignment with the nucleosomes at higher angles, but also to a higher probability of traversing the nucleus without hitting any DNA targets. For 1 MeV protons, the spherically weighted average RBE is 7 % higher and 22 % lower than the RBE for 0 and 90 degrees respectively. When simulating RBE, angular dependence of the dsb yields due to the nucleus model chosen should be investi-
gated and a spherically weighted average RBE should be reported.

**SP076.6 - DNA Damage Induced in Glioblastoma Cells by I-131: A Comparison between Experimental Data and Monte Carlo Simulation**

**Author(s):** Fereshteh Koosha

Medical Physics And Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN

**Objective:** The passage of ionizing radiation in living cells creates clusters of damaged nucleotides in DNA. In this study, DNA strand breaks induced by the beta particle of iodine-131 (I-131), have been determined experimentally and compared to Monte Carlo simulation results as a theoretical method of determining 131I damage.

**Materials and Methods:** For conducting this experimental study, Glioblastoma (GBM) cells were exposed to 10 mCi I-131, at a dose of 2 Gy, in order create single strand breaks (SSB) and double strand breaks (DSB) in the DNA of irradiated cells. Cells were evaluated quantitatively by the Fast Micromethod assay. The energy spectrum of electrons released in cells were obtained by the macroscopic Monte Carlo code (MCNP4c) and used as an input of the micro Monte Carlo code (MCDS). The percent of damage induced in cells was calculated by Manvity test.

**Results:** A significant reduction (p<0.05) in fluorescence intensity in irradiated cells compared to control cells as determined by the Fast Micromethod assay represented induced SSB and DSB damages in the DNA of irradiated cells. By comparing the experimental and theoretical results, the difference between the percent of SSB per Gy was about 7.4% and DSB was about 1% per Gy.

**Conclusion:** The differences in experimental and theoretical results may be due to the algorithm of applied codes. Since the Fast Micromethod and other experimental techniques do not provide information about the amount of detailed and complex damages of DNA-like base damages, the applied Monte Carlo codes, due to their capability to predict the amount of detailed damages that occur in the DNA of irradiated cells, can be used in in vitro experiments and radiation protection areas.

**SP076.7 - The stochastic extension of the Linear Quadratic model: Taking into account the uncertainty of radiobiological parameters.**

**Author(s):** Moises Saez-Beltran1, Francisco Saez-Beltran2, Francisco Fernandez Gonzalez3

1Servicio De Radiofisica Y Proteccion Radiologica, Complejo Asistencial Universitario de Salamanca, Salamanca/SPAIN, 2Servicio De Radiofisica, Complejo Asistencial de Zamora, Hospital Provincial, Zamora/SPAIN, 3Instituto Universitario Física Fundamental Y Matemáticas, Universidad de Salamanca, Salamanca/SPAIN

**Introduction:** We show the way to modify the Linear Quadratic model of cell survival used in Radiation Oncology to accommodate uncertainty in the radiobiological parameters (α, β). The objective is, given the probability distribution functions of α and β, find the probability distribution function of the biological equivalent dose, BED, and the probability of cell survival, p. And furthermore, find how this uncertainty propagates through a fractionation scheme. In this paper we show that this can be done in an explicit way without simulation.

**Materials and Methods:**

The stochastic extension of the Linear Quadratic model consist in promoting α, β, p, BED from single value variables to random variables α, β, p, BED. The delivered dose per fraction, d, is considered as a non-random parameter. For a single fraction, there is an analytical relationship between α, β and BED and p, so we can use the rules of probability to get a formula to obtain the probability distribution functions of p and BED from the corresponding probability distribution functions of α, β. For a fractionation scheme of dose, we have to consider sums of stochastic variables, that involves repeated convolutions of probability functions.

**Results:**

If we define equivalent treatments in the mean, for different fractionation schemes, we can recover the formulas of the usual Linear Quadratic model, substituting α, β by the expected value <α>, <β>. The variance of these treatments can also be shown to be different whenever the variance of α or β is different from zero. For a number of fractions large enough, p can be regarded as a log-normal stochastic variable, due to the central limit theorem.

**Discussion:**

We have described a analytical way to take into account the uncertainty of radiobiological parameters as probability distribution functions into the Linear Quadratic model, without Montecarlo simulation. This higher level of complexity gives in return better information of the effect of this uncertainty on the treatment outcome. Whether these stochastic extensions may explain data variability better than any more sophisticated “non-stochastic” radiobiological model is yet a matter of experiment.
SP077 - Radiation Oncology

SP077.1 - Assessment of CT to CBCT Non-Rigid Image Registration in Prostate Cancer Radiation Therapy
Author(s): Pawel Siciarz
Medical Physics, CancerCare Manitoba, Winnipeg/CANADA

Purpose: The goal of this project was to investigate the performance of three image registration algorithms implemented in two open source platforms: 3DSlicer and MedInria.

Material and Methods: The study describes CT to CBCT deformable registration by the application of following algorithms: two well known Affine and Fast Symmetric Forces Demons (3DSlicer) as well as Dense Anatomical Block Matching (MedInria) that is based on pyramidal block-matching approach. To the best of author knowledge it is the first study which attempts to investigate the performance of Dense Anatomical Block Matching Algorithm (DABM) for CT to CBCT deformable registration.

Pre-treatment CT (pCT) images of five prostate patients undergoing IMRT were selected for this work. Representative CBCT data sets were acquired in the middle of the radiotherapy treatment to provide the algorithms with realistically challenging registration problem. Deformable registration for each algorithm was followed by the initial Affine alignment of considered images. After registration, structures (GTV, Bladder and Rectum) delineated on pCT were first deformed using obtained vector fields, next propagated to CBCT images and finally compared to the contours delineated on CBCT by experienced Radiation Oncologist. The similarity between deformed CT (dCT) and CBCT images was also analysed.

Accuracy of registration was assessed by the application of the following metrics: Dice Coefficient and Mean Hausdorff Distance for structures comparison as well as voxel-to-voxel absolute intensity difference for dCT-CBCT images comparison. For visualization and structures comparison as well as voxel-to-voxel absolute intensity difference for dCT-CBCT images comparison, a surface map reflecting surface-to-surface distances for the closest surfaces can be created. The differences between considered organs contours as a surface map reflecting surface-to-surface distances for the closest surrounding points. The map of absolute discrepancies in image intensity between dCT and CBCT for selected image slices is also provided.

Results: Early results clearly indicates very promising performance of Dense Anatomical Block Matching method for challenging non-rigid pCT-to-CBCT registration compared to Affine and Demons algorithms which can be seen at the figure 1. This quick quality assessment is expected to be confirmed by more detailed analysis of proposed similarity metrics. Additionally, smooth and unfolding DVF-DABM shows the lack of any unphysical deformations.

SP077.2 - Use of flattening filter free photon beams for off-axis targets in conformal and stereoelectric body radiation therapy
Author(s): Ashley Smith1, Christopher Serago2, Siyong Kim1, Kathleen Hintenlang1, Michael Heckman2, David Hintenlang3
1Radiation Oncology, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, 2Radiation Oncology, College Of Medicine, Virginia Commonwealth University, Richmond/VA/UNITED STATES OF AMERICA, 3Biomedical Statistics And Informatics, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, 4Biomedical Engineer, University of Florida, Gainesville/UNITED STATES OF AMERICA

Dynamic conformal arc therapy (DCAT) and FFF beams are commonly adopted for efficient conformal dose delivery in SBRT. Off-axis geometry (OAG) may be necessary to obtain full gantry rotation without collision, which has been shown to be beneficial for peripheral targets using flattened beams. We investigated dose distributions in OAG using FFF, and the effect of mechanical rotation induced uncertainty.

Sphere targets (2, 4, and 6 cm diameter) were placed at three locations (central axis, 3 cm, and 6 cm off-axis) in a representative patient CT set. DCAT plans were obtained for 6X, 6FFF, 10X, and 10FFF. Homogeneity index (HI), conformity indices (CI), and beam on time (BOT) were calculated. Mechanical rotation induced uncertainty was evaluated using five SBRT patient plans with laterally located tumors. For each, a plan was generated using FFF beams for OAG and CAG. Each was replanned to account for one degree collimator/couch rotation errors during delivery. Prescription isodose coverage, CI, and lung dose were evaluated.

HI and CI values were similar for flattened and unflattened beams; however, 6FFF provided slightly better values than 10FFF in OAG. For all plans HI and CI were acceptable with the maximum difference between flattened and FFF beams being 0.1. FFF beams showed better conformity for low doses and small targets. Variation due to rotational error for isodose coverage, CI, and lung dose was generally smaller for CAG compared to OAG, with some of these comparisons reaching statistical significance. However, variations in dose distributions for either technique were small and not clinically significant.

FFF beams showed acceptable dose distributions in OAG. 10FFF provides more dramatic BOT reduction, but generally provides less favorable dosimetric indices compared to 6FFF in OAG. Mechanical rotation induced uncertainty had an increased effect for OAG compared to CAG; however, variations for either treatment technique were minimal.

SP077.3 - Dosimetric evaluation of the interplay effect for non-gated VMAT treatment of moving targets with high dose rate FFF beams
Author(s): Ashley Smith1, Christopher Serago1, Kathleen Hintenlang2, Siyong Kim1, David Hintenlang3
1Radiation Oncology, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, 2Radiation Oncology, College Of Medicine, Virginia Commonwealth University, Richmond/UNITED STATES OF AMERICA, 3Biomedical Engineering, University of Florida, Gainesville/UNITED STATES OF AMERICA

Purpose: Interplay effects exist between multi-leaf collimator movement and tumor motion when treating moving targets with intensity modulated radiation therapy. Dose deviations caused by the interplay effect can be decreased by reducing the dose rate. It is questionable whether flattening filter free (FFF) high dose rate will increase dose deviations caused by the interplay effect for volumetric modulated arc therapy (VMAT). This work evaluates the interplay effect using a moving phantom to simulate respiratory tumor motion for non-respirato-
ry-gated VMAT treatment using FFF beams, and investigates the impact of dose rate.

METHODS

Two VMAT plans were selected from lung patients treated with 6 MV FFF beams. Dose distributions were measured using a 2D ion chamber array placed on a motor-driven motion platform. Respiratory phase was accounted for by dividing the breathing cycle into 8 equally spaced phases and irradiation was initiated at each of the phases. The 8 starting phases were used to simulate the clinical situation of starting the treatment at a random phase in the patient breathing cycle. All fields were delivered in their treatment geometries with and without phantom motion using 3 dose rates: 1400, 600, and 400 MU/min.

Measured dose was compared to planned dose using gamma analysis (3%/3mm), percent of pixels within 5% of pixel dose, and percent of pixels within 10% of pixel dose. Calculations were done for the 8 initial starting phases and repeated for a random sampling of starting phases for 1000 trials. Target coverage was evaluated by the dose difference for four points at the center of the target. Four points at the periphery of the target were used to evaluate planning target volume margin.

RESULTS

Results for 1000 trials of randomly selected motion phases are reported in Table 1. The delivered dose compared to planned dose in the center of the target region was within 5.0% for the static phantom condition and 7.4% for the moving phantom condition. At the periphery of the target the delivered dose differed from planned dose by -0.9% to 13% for the static condition and -28.8% to 39.7% for the moving condition.

CONCLUSION

Our results indicate the interplay effect had an impact on non-gated VMAT when treating a moving target with FFF, however using high FFF dose rate did not increase dose deviations compared to lower dose rates. The impact of the interplay effect on target coverage is acceptable, as long as sufficient margin is given.

SP077.4 - In vivo Image Guided Brachytherapy Verification (IGBV) in high dose rate prostate brachytherapy – Initial Clinical Experience

Author(s): Ryan L. Smith1, Annette Haworth2, Jeremy L. Millar1, Michael L. Taylor3, Rick D. Franchi1
1William Buckland Radiotherapy Centre, The Alfred Hospital, Melbourne/AUSTRALIA, 2Physical Sciences, Peter MacCallum Cancer Centre, East Melbourne/VIC/AUSTRALIA, 3School Of Applied Sciences, RMIT University, Melbourne/VIC/AUSTRALIA

Aim.

High dose rate (HDR) prostate brachytherapy treatment is widely practiced and is a well-established radiotherapy technique. Usually delivered in large dose fractions, poor execution in the delivery of a planned treatment would have significant clinical impact on the patient. The frequency and type of errors that may occur in HDR brachytherapy treatment are mostly unknown as there exist limited options for independent routine monitoring of treatment delivery to identify potential errors and ensure patient safety. We report our initial clinical experience with a novel, non-invasive, source-tracking system based on a flat panel detector (FPD) for treatment verification in HDR prostate brachytherapy: Image Guided Brachytherapy Verification (IGBV).

Materials & Method.

For IGBV, a FPD was mounted in our brachytherapy treatment couch under a customised carbon fibre couch top assembly. Six prostate patients (10 treatment fractions) were included in this clinical study of the IGBV system. At treatment, each patient was aligned on the brachytherapy couch with the target region (prostate) centred on the sensitive imaging area of the FPD. As the HDR treatment proceeded, images of the source position were acquired with the FPD in the form of patient exit radiation. These images were post-processed to determine the position of the source inside the patient and were compared to the treatment plan in order to identify potential errors and verify correct treatment delivery.

Results.

The measured source dwell positions confirmed correct transfer tube connection, afterloader indexer length, source step size and patient/plan selection. The mean linear distance between measured and planned source dwell positions was 2.37 mm (s.d. 0.96mm), after rigid registration with the treatment plan. The average dwell step size across all measured catheters was 2.54 mm (s.d. 0.24mm, n=112). The absolute position of the measured dwell, together with the implanted gold fiducial markers, visible on a pre-treatment radiograph, provided verification of programmed treatment indexer length and therefore delivery to the correct anatomical location. This unique brachytherapy verification process is non-invasive, with the patients virtually unaware of the verification imaging that is occurring during treatment delivery. The total impact on procedure time was less than 15 minutes.

Conclusion.

This novel, non-invasive HDR brachytherapy treatment verification system, IGBV, was implemented clinically, providing confirmation of many treatment parameters by tracking the position of the HDR source as treatment was delivered. An independent treatment monitoring system, such as the one described here, could validate the treatment delivery process in real time, enabling a safety interlock system. The clinical experience with the IGBV system provided confirmation that the treatment was delivered free of potential human related errors. This concept and system will meaningfully improve safety standards by allowing routine treatment verification in HDR brachytherapy across a range of clinical applications.

SP077.5 - Electronic Portal Imaging Device Dosimetry for IMRT: a Review on Commercially Available Solutions

Author(s): Omemh Bawazeer1, Sisira Herath2, Siva Sarasananda-jah1, Pradip Deb3
1School Of Medical Radiation, RMIT University, Melbourne/AUSTRALIA, 2Radiation Oncology, Peter MacCallum Cancer Centre, Melbourne/AUSTRALIA

Much research has been conducted about the utilization of electronic portal imaging devices (EPID) for dose verification during radiotherapy treatment. Currently a number of commercial solutions are available; Portal Dosimetry, EPI Dose, Epiq, Dosimetry Check, and EPIgray software. Results from separate studies on clinical applications of these solutions are published. The objective of this paper is to review the accuracy of these dosimetry solutions when used for intensity modulated radiotherapy technique (IMRT). Although each solution has a different approach to dose verification, most of the IMRT dosimetry verification results are highly satisfactory. However, performance of one solution is less satisfactory when the patient-couch attenuation occurs. Moreover, none of these solutions correct the back scatter effect resulted from supporting arm. In addition, there are no comparative studies currently available about the accuracy of these solutions except one paper that compared Portal Dosimetry and EPI Dose reporting the major differences between these systems. Further studies are needed to compare the accuracy of these commercially available EPID dosimetry solutions.

SP077.6 - The Nano-X Radiotherapy Machine: Lean Innovation Transforming Global Access to Cancer Care

Author(s): Paul Keall1, Enid Eslick1, Peter Lazarakis1, Michael Jackson1, Ilana Feain2
1Radiation Physics Laboratory, University of Sydney, University of Sydney/AUSTRALIA, 2University of New South Wales, Sydney/AUSTRALIA

The Nano-X vision is to level the playing field in global access to radiotherapy. Where cancer patients in low and middle income countries have access to appropriate treatment and care, where the machine is designed from the ground up to deliver an affordable and viable solution for the people that need treatment, where they needs treatment, independently of where highly trained workforces live.

The Nano-X Solution

Nano-X, which will enter the international market by 2020, will launch on a wave of global awareness around this epidemic. Nano-X alleviates major obstacles to global radiotherapy utilization with lean innovation and a compact, affordable system for low and middle-income countries with drastically simplified hardware and workflow. A Nano-X schematic is shown: a full clinical prototype is now under construction and the shielded bunker is complete.
**SP077.7 - Development of an MR and CT compatible non-invasive temperature based optical fiber respiration sensor for use in radiotherapy**

**Author(s):** Ashley Smith¹, Siyong Kim², Christopher Serago¹, Kathleen Hintenlang¹, Robert Pooley³, David Hintenlang⁴

¹Radiation Oncology, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, ²Radiation Oncology, College Of Medicine, Virginia Commonwealth University, Richmond/VA/UNITED STATES OF AMERICA, ³Radiology, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, ⁴Biomedical Engineering, University of Florida, Gainesville/UNITED STATES OF AMERICA

We have developed a non-invasive temperature based respiration sensor to track the breathing cycle during respiratory gating that is not subject to the limitations of an external marker. The sensor tracks the breathing cycle by measuring the temperature of inspiratory and expiratory air (Figure 1). Because it doesn’t rely on movement of the abdomen it can be used with forced shallow breathing (FSB) or thermoplastic body mask immobilization. The sensor is compatible for use in CT, MR, and linear accelerator environments.

Respiration signals were tested with five volunteers using FSB, and compared to simultaneously recorded signals from an external marker. Temperature readings were also tested in a CT, MR, and linear accelerator environment. The sensor’s effect on image quality was evaluated for CT and MR.

The temperature sensor successfully recorded the breathing cycle for all volunteers, while the external marker had one failure (Figure 2). Fluctuations in temperature sensor signals were similar to background in both a CT and MR environment. There was greater signal fluctuation when the sensor was placed in a high energy linear accelerator field and given a high dose. The fluctuation was acceptable when the sensor was outside the radiation field. It is recommended that the sensor be placed outside the treatment field during treatment. Image quality was not affected by the temperature sensor for CT or MR.

**Conceptual Innovation:** Nano-X will deliver a paradigm shift in radiation oncology by enabling affordable, accessible radiotherapy in resource-limited areas where capital costs and on-site operations are major issues. Nano-X increases patient throughput and decreases on-site staffing using sophisticated algorithms and leveraging telemedicine to enable centralised planning and local treatment with automated decision making. **Methodological Innovation:** Nano-X will treat patients with a fixed vertical beam and a patient rotation couch. This reduces costs enormously by reducing the (i) engineering complexity, (ii) size and radiation shielding requirements of the room (iii) onsite staffing requirements and (iv) time-consuming and inconvenient patient immobilisation procedures and treatment planning. **Technological Innovation:** For Nano-X, tumour motion will be substantial as patients themselves are rotated. The technological innovations in Nano-X are our algorithms for real-time image guidance and dynamic adaptation of the treatment beam to account directly for tumour motion.
We have shown that the temperature based respiration sensor can successfully track breathing cycles even when external markers fail. Performance is maintained in MR and ionizing radiation environments; however it is recommended that it not be used in the direct path of a high energy beam. We have verified that respiratory signals can be obtained without deterioration of CT or MR images. It is anticipated that this device would be highly suitable for respiratory gating in radiation therapy.
SP078 - Brachy Therapy: Part 2

SP078.1 - The Effect of Bladder Preparation on Motion of Organs at Risk in High Dose Rate Gynecological Brachytherapy

Author(s): Parisa Sadeghi1, Robyn Banerjee2, Tien Phan1, Majed Alghamdi2, Amandeep Taggar2, Wendy L. Smith1

1Physics And Astronomy, University of Calgary, Calgary/Canada, 2Radiation Oncology, Tom Baker Cancer Centre, Calgary/AB/Canada

Introduction: High Dose Rate (HDR) brachytherapy is part of the treatment protocol for advanced cervical cancer. The planning process for Magnetic Resonance (MR) guided treatment requires both Computed Tomography (CT) and MR imaging. This combines the high soft tissue contrast of the MR images with the ability of the CT scan to visualize the applicator inside the patient. However, this dual imaging requires multiple patient transfers and increases the overall patient motion. This can lead to changes in both the position and volume of the organs at risk (OARs) in the pelvic region, such as the rectum and bladder.

The purpose of this study is to evaluate the effect of bladder filling (often used to reduce bowel dose) on bladder motion, and quantify the motion of the rectum during HDR brachytherapy of cervical cancer.

Methods: A total of 15 cervical cancer patients were included in this study. Nine patients were treated without introducing bladder filling. Six patients had their bladder contents emptied and re-filled to a specific volume (120 – 200 cc). The change in bladder volume and center of mass (CM) position between the MR and CT imaging sessions, as well as the concordance index (CI) of the contoured bladders on both image sets were calculated using the Eclipse treatment planning system by Varian.

Results and Discussion: It is evident, from the data presented in Table 1 that the prepared bladders display a smaller change in volume compared to the bladders without the filling. In addition, prepared bladders show a mean positional change of 4.2 mm (range: 1.6-8.5 mm), while a positional change of 5.3 mm (range: 1.5-15.4 mm) is observed in the absence of bladder filling. This is interesting because the filling implemented for bowel sparing seems to have the added benefit of reducing bladder mobility. Also the prepared bladders seem to have a higher CI value. The rectum shows an overall positional change of 6.6 ± 4.6 mm over the whole patient population.

Conclusion: Our results clearly display a trend where the bladder preparation leads to a smaller bladder motion, smaller volume change, and higher CI. Although preliminary statistical analysis did not reveal any significant difference between the two bladder preparation protocols, a larger sample size could provide more conclusive results.

SP078.2 - Retrospective Monte Carlo dose calculations for permanent implant prostate brachytherapy using 125I

Author(s): Paul Soubiran1, Justin Sutherland1, Nelson Miksyz2, Ali-Reza Mehan Haidari3, Rowan Thomson3, E Chooan1, Gad Perry1, Joanna Cygler1

1Radiation Medicine Program, The Ottawa Hospital Cancer Centre, Ottawa/CANADA, 2Physics, Carleton University, Ottawa/ON/CANADA

Clinical dose calculations for low dose-rate (LDR) prostate brachytherapy are currently performed following the protocols defined by the American Association of Physicists in Medicine (AAPM) Task Group no. 43 (TG-43) formalism. Using the TG-43 formalism, absorbed dose is calculated in a homogeneous water environment so the effects of tissue heterogeneities, interseed attenuation, and the finite dimensions of patients are not accounted for. This work retrospectively investigates differences between TG-43 and Monte Carlo (MC) calculated dose distributions for 105 patients treated with LDR prostate brachytherapy at The Ottawa Hospital.

Each of the 105 patients used in this study had a prescribed dose of 145 Gy (Drx) to the prostate through implantation of 125I seeds (Model 6711 RAPID Strand™). Treatment planning and seed implantations were performed in real-time using ultrasound images. MC calculations were performed using the EGSnrc user-code BachyDose. Computational phantoms for each patient were generated from CT images acquired 1 month post-implant by a Philips Brilliance CT scanner – Big Bore. Material compositions were assigned to each voxel within image contours based on CT number: prostate and calcification within prostate contours, air and muscle within rectum contours, urinary bladder within bladder contours, and ICRU 46 soft tissue and bone in the remainder of the phantom. CT number thresholds between tissue assignments were assigned consistently between patients and were determined by manual investigation of CT scans for several patients. The mass density of each voxel was derived from a scanner calibration of Hounsfield Units to density. To avoid misassignment of voxels to calcification and since BrachyDose models full seed geometries, seeds and metallic artifacts were removed from scans prior to tissue assignment by over-riding CT numbers above a threshold in the vicinity of the seeds. Dose to medium was calculated with sufficient histories to achieve a statistical uncertainty of less than 2% in prostate volumes.

Dose distributions calculated with BrachyDose differed considerably from those calculated with TG-43. The patient-averaged minimum dose to 90% of the target volume (D90) was 9.5 Gy lower as calculated by BrachyDose compared to TG-43. The average D99 was 52 Gy less than Drx as calculated by BrachyDose compared to 45 Gy less than Drx as calculated by TG-43. Similarly, the patient-averaged percentage volume that received at least 100% of the prescription dose (V100%) was 4% lower as calculated by BrachyDose compared to TG-43. While doses to organs at risk (OAR) also differed...
between BrachyDose and TG-43 calculated distributions, the differences were smaller. The patient-averaged highest dose received by 1 cc (D1cc) of the rectum was 103 Gy as calculated by BrachyDose and 110 Gy as calculated by TG-43; a 6.5% difference which may be clinically significant. D1cc for the bladder was 86 Gy for BrachyDose versus 88 Gy for TG-43 calculations, which is not clinically significant.

Retrospective MC calculated dose distributions for 105 Ottawa Hospital patients treated with LDR prostate brachytherapy showed a decrease in average dose coverage of target volumes and OARs as compared with TG-43 calculated dose distributions.

SP078.3 - Combining doses for prostate cancer patients receiving external beam radiotherapy and a HDR brachytherapy boost: Dosimetric parameters and dose-surface maps for patients with and without late rectal bleeding

**Author(s):** Calvin R. Moulton1, Michael House1, Victoria Lye2, Colin Tang2, Michele Krawiec2, Tim St Pierre1, David J. Joseph2, James W. Denham3, Martin A. Ebert2

1School Of Physics, The University of Western Australia, Crawley/ WA/AUSTRALIA, 2Radiation Oncology, Sir Charles Gairdner Hospital, Nedlands/WA/AUSTRALIA, 3School Of Medicine And Population Health, The University of Newcastle, Callaghan/NSW/AUSTRALIA

**OBJECTIVE:** Are post-registration rectum dosimetric parameters and rectum dose-surface maps (DSM) different for groups of patients who did or did not have late bleeding?

**Methods:** 91 patients received external beam radiotherapy (EBRT) in 23 fractions of 2 Gy and high-dose-rate (HDR) brachytherapy in 3 fractions of 6.5 Gy. The EBRT CT was registered to the HDR CT with a rigid plus deformable multi-pass method (RD) or a rigid plus scale plus deformable multi-pass (RSD) method in Velocity Advanced Imaging. The unregistered EBRT and registered HDR dose distributions were summed after converting to equieffective doses at 2 Gy/fraction (α/β = 3 and 5.4). The V1Gy to V100Gy (increment=1) and D1% to D100% (increment=1), D1cc, D2cc, D5cc and D10cc were calculated. Rectum DSMs were obtained by virtually unfolding the rectum surface dose slice-by-slice. Patients were classed into toxicity or no toxicity groups if they did or did not have a grade 2 LENT-SOMA rectal bleed from the period 3 months after radiotherapy onwards. The DSMs were spatially analysed by thresholding DSMs from 1 Gy to 100 Gy (increment=1). This analysis included the inferior-superior extent, left-right extent, area, perimeter, compactness, circularity and ellipse fit parameters. Significance (p<0.05) for median comparisons between groups was assessed via two-sided Mann-Whitney U-tests.

**Results:** The dosimetric and DSM results in the figure are for the RSD registration, HDR dose calculated with the Acuros algorithm and an α/β of 3; however, results were similar for alternatives. The V44Gy, V45Gy, V46Gy to V71Gy, D1% to D28%, D1cc, D2cc, D5cc and D10cc were significantly greater for toxicity (N=73) groups. Patients with toxicity had significantly greater left boundaries, greater right boundaries, greater widths and greater perimeters for various DSM isodose contours (e.g. 51-66 and 83 Gy). The ellipse fits at a number of dose thresholds (e.g. 83 Gy) indicated significantly greater lateral extent, greater eccentricity and greater horizontal orientation for bleeders. The lateral centroid components for some dose thresholds (e.g. 83 Gy) were significantly further to the right for bleeders. The proportions of ellipses filled by various thresholded doses (e.g. 50 Gy) were significantly greater for bleeders.

**Conclusion:** Multiple dose-volume parameters, derived from registered plans, correlated with bleeding. The lateral coverage of intermediate and high-dose regions was greater and located further to the right for bleeders. For bleeders, the doses in high-dose regions were greater and more contained within fitted ellipses.

SP078.4 - Implementation of Permanent Breast Seed Implants in British Columbia: Innovation and Early Results

**Author(s):** Michelle Hilts1, Deidre Batchelor1, Daniel Morton2, Juanita Crook2

1Medical Physics, BC Cancer Agency - Southern Interior, Kelowna/ CANADA, 2Physics And Astronomy, University of Victoria, Victoria/ CANADA, 3Radiation Oncology, BC Cancer Agency - Southern Interior, Kelowna/CANADA

**Purpose:**

Permanent breast seed implant (PBSI) is an attractive option for women with early stage breast cancer as the procedure is completed in a single outpatient session. In 2012 the BC Cancer Agency became only the second institution worldwide to offer this novel technique pioneered in Toronto. In this work we present technique innovations introduced at BCCA as well as preliminary results from our first 15 patients.

**MATERIALS AND METHODS:**

Modelled after the technique introduced by Pignol et al, we use a template and US guided technique to implant needles pre-loaded with Pd-103 into the breast. CT planning (MIM Symphony) is undertaken to deliver 90Gy to a PTV, seroma+1.25cm cropped to skin and chestwall. A pre-treatment simulation step is included to check template position and transfer key landmarks from the treatment plan onto the skin. In the operating room a portable laser is used to confirm positioning and US is used throughout the procedure to monitor needle placement. Post-implant dosimetry is assessed using CTs obtained on day of implant (day0:reported here) and one month post-implant. Deformable image registration is used to define the post-implant seroma from the pre-implant contour. Implant quality is assessed on an evaluative PTV (PTVeval), seroma+0.5cm. In house software was utilized to measure seed displacements (planned to implanted positions) in 10 cases. Patient satisfaction is also reported.
Results:

Pre-implant volumes ranged from 4.1–20.2cc (median 7.0cc) and 31.4–114.2cc (median 47.4cc) for seroma and PTVs respectively. PTVs were well covered with V100 (mean±SD) of 96.1±2.7% using 77±22 seeds in 17±5 needles. Post-implant PTVal eval dosimetry (day0) for all patients was (mean±SD): 90.4±9.4%, 86.9±10.8% and 64.4±14.9% for V90, V100 and V150 respectively and 87.1±25.3Gy for D90%. The corresponding PTVal eval coverage (mean±SD) for the last 8 implants illustrates rapid convergence to consistently high quality implants: 96.5±2.6%, 93.6±4.6% and 70.9±12.1% for V90, V100 and V150 respectively and 103±16Gy for D90%. Mean seed displacement was 0.9±0.5cm for the 10 patients where seed matching was performed. All patients were very or extremely satisfied with the procedure, citing the single day treatment as a highlight.

Conclusions:

These early results indicate that PBSI is a safe and desirable treatment option for women with low risk breast cancer and technical innovation aimed at increased technique reproducibility has contributed to a rapid learning curve. Our aim, through ongoing technical innovation, is to continue to improve the standardization and reproducibility of PBSI to ultimately enable widespread implementation.

Results: The squared difference criteria for the median dosimetric values were not satisfied for some dosimetric parameters and toxicity criteria. The α/β for the dosimetric parameters, toxicity criteria and TG43/Acuros algorithm options varied from 0.710 to 4.84. The variability was greater across the parameters and toxicity criteria. The α/β (95% CI) for the parameters (toxicity criteria) were 3.98 (0.260-10.1), 0.710 (0.100-6.18), 1.49 (0.090-10.7) and 3.51 (2.45-8.03) for the D1cc (≥1), D2cc (≥1), D5cc (≥2) and D10cc (≥3) options applied with the Acuros algorithm. The mean α/β and mean 95% CI across the parameters, toxicity criteria and TG43/Acuros algorithm options were 2.75 and 0.834–8.94.

Conclusion: The estimated mean α/β was 2.75 for late rectal bleeding. A conclusion on the early/late responding nature of the rectum was not feasible due to variability across parameters and wide confidence intervals. An increased sample size may result in more consistent and precise values across the dosimetric parameters and toxicity criteria.

ACKNOWLEDGEMENTS: NHMRC (1006447) and University of Western Australia.

SP078.5 - Estimation of α/β for late rectal bleeding via minimum dosimetric differences for prostate cancer patients treated with external beam radiotherapy versus a HDR brachytherapy boost after external beam radiotherapy

Author(s): Calyn R. Moulton1, Michael House1, Victoria Lye2, Colin Tang3, Michele Krawiec4, Angel Kennedy5, Tim St Pierre5, David J. Joseph5, James W. Denham2, Martin A. Ebert1

1School Of Physics, The University of Western Australia, Crawley/ WA/AUSTRALIA, 2Radiation Oncology, Sir Charles Gairdner Hospital, Nedlands/WA/AUSTRALIA, 3School Of Medicine And Population Health, The University of Newcastle, Callaghan/NSW/AUSTRALIA

OBJECTIVE: To estimate the α/β for late rectal bleeding via the difference in dosimetric parameters for patients treated with external beam radiotherapy (EBRT) versus a combined treatment of EBRT and high-dose-rate (HDR) brachytherapy.

Methods: In the RADAR trial, 723 patients received 66, 70 or 74 Gy (2 Gy/fraction) of EBRT and 91 patients received 46 Gy (23 fractions) of EBRT and 19.5 Gy (3 fractions) of HDR brachytherapy. HDR dose was calculated with both the Acuros and TG43 algorithms. For combined treatments, the EBRT CT was registered to the HDR CT in Velocity Advanced Imaging. The rectum D1cc, D2cc, D5cc and D10cc were calculated for patients receiving EBRT only and patients receiving combined EBRT/HDR. These parameters were correlated with bleeding for patients receiving combined EBRT/HDR. Patients from the two treatments were classed into toxicity groups if they had at least a certain grade (1, 2, or 3) LENT-SOMA rectal bleed from the period 3 months after radiotherapy onwards. The toxicity numbers for the EBRT only/combined treatment groups were 343/374, 18/183 and 5/66 for grades ≥1, ≥2 and ≥3. The parameters for patients with toxicity after EBRT only versus after combined EBRT/HDR treatments were compared as follows. (1) The medians of dosimetric parameters for the EBRT toxicity group were converted to equieffective doses at 2 Gy/fraction with α/β from 0-11 (increment=0.01). (2) This conversion was also applied to medians of the dosimetric parameters from the unregistered EBRT and registered HDR components for the combined treatment toxicity group. (3) The total median parameters for the combined treatment toxicity group were obtained by summing the converted median dosimetric parameters for the unregistered EBRT and registered HDR components for the combined treatment toxicity group. (4) The α/β with the smallest squared difference between the median converted dosimetric parameters for the two groups was determined and accepted if the squared difference was less than 0.01. (5) Bootstrapped 95% confidence limits (CI) for the α/β were calculated via (1)-(4) after resampling the two groups with replacement (10,000 resamples).

Results: The α/β (95% CI) for the parameters (toxicity criteria) were 3.98 (0.260-10.1), 0.710 (0.100-6.18), 1.49 (0.090-10.7) and 3.51 (2.45-8.03) for the D1cc (≥1), D2cc (≥1), D5cc (≥2) and D10cc (≥3) options applied with the Acuros algorithm. The mean α/β and mean 95% CI across the parameters, toxicity criteria and TG43/Acuros algorithm options were 2.75 and 0.834–8.94.

Conclusion: The estimated mean α/β was 2.75 for late rectal bleeding. A conclusion on the early/late responding nature of the rectum was not feasible due to variability across parameters and wide confidence intervals. An increased sample size may result in more consistent and precise values across the dosimetric parameters and toxicity criteria.

SP078.6 - Failure Mode and Effects Analysis (FMEA) for improving quality assurance for Image-Guided High Dose Rate (HDR) brachytherapy

Author(s): Shada Wadi-Ramahi, Waleed Al-Najjar, Belal Moftah

Biomedical Physics, King Faisal Specialist Hospital and Research Center, Riyadh/SAUDI ARABIA

Purpose:

To evaluate and develop quality assurance (QA) for image-guided high dose rate (HDR) brachytherapy by applying the failure mode and effects analysis (FMEA).

Method:

We started by mapping the major process tree of HDR brachytherapy, and highlighting the image-dependent steps. “Wrong Treatment Site” was identified as being the ultimate end-point that might result from errors in imaging procedures, and fault tree analysis (FTA) for this error was mapped with all the branches leading to it. The use of conventional imaging (2D) with isocentric and non-isocentric machines was also included for completeness. Potential risk for
The FTA, revealed a point during the HDR process (nodes 29 and 30) where QA is lacking. Those are non-image related; however, the error can be stopped from propagating by implementing a pre-treatment image verification procedure, which can be achieved by several methods depending on the user’s capabilities.

Conclusion: We have applied FMEA process to image-guided HDR brachytherapy. The fault tree for “wrong treatment site” error identified areas of potential high risk and exposed areas where QA was lacking in the whole procedure. This helped us in re-prioritizing our QA procedures and guidelines.

Results:
Fourteen major steps were identified: TPS commissioning, source installation and initial QA, patient diagnosis and selection, applicator insertion, primary image set acquisition, secondary image set acquisition, Image transfer and registration, organ delineation, applicator and coordinate system definition, plan optimization and dose calculation, plan transfer to treatment console station, source connectivity to patient, image verification of applicator position before treatment, and finally treatment delivery. Of these steps, six are image dependent and all leads to one error “Wrong treatment site”. The FTA for “wrong treatment site” identified 30 potential failure nodes (2 are machine related, the rest are human related), see attached figure. Out of the 30, eleven are non-image related. Total RPNs ranged from 11 to 254. RPN for image arm ranged from 11 to 254, whereas for non-images RPN ranged from 45 – 192. RPN higher than 100 was considered potential for high risk. The errors were grouped into three major groups (human, procedural or machine). For each set, we took the analysis further by proposing corrective actions, such as development and implementation of departmental guidelines and QA.
Tumor motion due to respiratory motion can lead to dosimetric errors in the delivery of radiotherapy treatments. Respiratory gating can be used to address this issue but requires external markers or motion surrogates to monitor the breathing motion. However, these are not always well correlated to the true position of the tumor. We present a feasibility study of respiratory gated radiotherapy using a real-time positron emission tracking system.

The tracking system, called PeTrack, uses implanted low activity positron emission markers and position sensitive gamma ray detectors to track breathing motion in real-time. A LabVIEW interface is developed to synchronize gating between the signal from PeTrack and the NRC Elekta Precise linac. Prototype PeTrack detectors were mounted on an aluminum frame surrounding a dynamic anthropomorphic thorax phantom (Figure 1). Dose was delivered to the phantom in 500 monitor unit increments with a 3x3 cm$^2$ photon beam and with 6 and 10 MV nominal beam energies. Radiochromic films were inserted in the phantom to measure spatial dose distributions. The phantom lung insert was translated in the inferior/superior direction with sinusoidal and real patient breathing motion (±10 mm amplitude). The motion was tracked using a small $^{22}$Na fiducial marker (0.43 MBq activity) embedded in the lung insert. The beam was turned off when the marker was outside of a 5-mm one dimensional gating window.

Clear improvement of the dose distribution is observed between gated and non-gated delivery (Figure 2). Monitoring of the beam on/off times show synchronization with the location of the marker within the latency of the system.
A new real-time IGRT system, kilovoltage intrafraction monitoring (KIM), is undergoing clinical evaluation through a first-in-world prospective clinical trial for prostate cancer patients. KIM uses kV fluoroscopy to monitor, in real-time, the 3D position of radio-opaque markers implanted into the prostate target. The real-time target position is used to guide the treatment: if the prostate moves outside the tolerance (motion exceeding 3mm for 5 seconds) the beam is paused and the patient is repositioned. The goal of this study is to investigate the localisation accuracy and dosimetric impact of the KIM system, in planned 30-patient gated prostate cancer radiotherapy trial.

To date, three patients have completed their 40-fraction treatments. Simultaneous intra-fraction kV and MV images from the 116 fractions were used offline to measure the accuracy of the KIM real-time measurements. The measured triangulated kV-MV marker positions were considered to be ground truth, and were compared to the KIM measurements. For the dosimetry, dose delivered during each fraction with KIM was measured using a motion-synchronized isocenter shift dose reconstruction method. In the fractions with a gating event, dose reconstruction was also carried out for a simulated treatment scenario with no KIM gating correction representing the current standard of care. Target and normal tissue dose volume statistics were compared for the planned treatment delivery, delivery with KIM gating and delivery with no KIM correction (see figure 1). KIM has a finite gating threshold and therefore, in the presence of motion, it will deviate from the planned treatment.

The mean error ± standard deviation of KIM in the LR, SI and AP directions was 0.14±0.50, 0.38±0.27, and -0.46±0.45 mm respectively. In total, 14 fractions had successful KIM gating corrections. Prostate motion with KIM corrections and simulated with no KIM corrections were 1.9±1.2 mm and 3.8±1.4 mm respectively. Mean (range) differences between the planned and KIM corrected doses and the planned and no KIM correction doses were respectively: PTV D95% -1.4 (-3.4, 0.7) & -3.1 (-10.9, -0.7); CTV D100% -0.8 (-2.8, 0.7) & -0.1 (-7.0, 1.9); rectum V65% -3.5 (-9.4, 5.7) & -4.9 (-11.2,18.7); and bladder V65% 1.58 (-0.9, 5.8) & 2.8 (-10.0, 10.4).

In conclusion, the results demonstrated that both the accuracy and precision of KIM system are sub-millimetre, and KIM gating improves the agreement between the planned and delivered treatments for prostate radiotherapy. The KIM technology has wide-scale applicability as it is implemented on a standard linear accelerator with little modification.

Purpose: Irregular breathing can influence the outcome of four-dimensional computed tomography imaging for causing artifacts. Audio-visual biofeedback systems associated with patient-specific guiding waveform are known to reduce respiratory irregularities. In Japan, abdomen and chest motion self-control devices (Abches), representing simpler visual coaching techniques without guiding waveform are used instead; however, no studies have compared these two systems to date. Here, we evaluate the effectiveness of respiratory coaching to reduce respiratory irregularities by comparing two respiratory management systems.

Methods: We collected data from eleven healthy volunteers. Bar and wave models were used as audio-visual biofeedback systems. Abches consisted of a respiratory indicator indicating the end of each expiration and inspiration motion (Fig. 1). Respiratory variations were quantified as root mean squared error (RMSE) of displacement and period of breathing cycles.

Results: All coaching techniques improved respiratory variation, compared to free-breathing. A typical case study showing improvements regarding respiratory irregularity is summarized in Fig. 2. Displacement RMSEs were 1.43±0.84, 1.22±1.13, 1.21±0.86, and 0.98±0.47 mm for free-breathing, Abches, bar model, and wave model, respectively. Free-breathing and wave model differed significantly. Period RMSEs were 0.48±0.47 mm for free-breathing, Abches, bar model, and wave model, respectively. Free-breathing and wave model differed significantly. Period RMSEs were 0.48±0.47 mm for free-breathing, Abches, bar model, and wave model, respectively. For variation in both displacement and period, wave model was superior to free-breathing, bar model, and Abches. The average reduction in displacement and period RMSE compared with wave model were 27% and 47%, respectively.

Conclusions: This study was to evaluate the efficacy of audio-visual biofeedback to reduce respiratory irregularity compared with Abches. Our results showed that audio-visual biofeedback combined with a wave model can potentially provide clinical benefits in respiratory management, although all techniques could reduce respiratory irregularities.
difference between the predicted position and the modeled position calculated after 115 ms had elapsed. We computed model correlation errors using the difference between the correlation model’s position estimate and the internal fiducial position from x-ray imaging. To estimate overall uncertainty, we quadratically summed the correlation, prediction and end-to-end targeting error (±0.5 mm) in each direction. We also tested the linear correlation between target amplitude and tracking errors for each direction.

Results showed that the cranio-caudal direction exhibited the greatest correlation and prediction errors, but total radial error was less than 5 mm (Table 1). Significant weak correlations (r = 0.08 – 0.19, p<0.0001) existed between target amplitude and correlation errors in all directions except left-right; whereas, strong correlations existed with prediction errors (r = 0.55 – 0.67, p<0.0001) for all directions.

Based on the overall 3D radial position errors, results suggest that for 95% of the beam delivery time the target centroid will be within 4.6 mm of the planned target volume. These results along with consideration for internal fiducial migration, target rotation and liver deformation may help guide planning target volume expansion.

SP079.4 - Tracking Accuracy for Robotic Radiosurgery in the Liver

Author(s): Jeff D. Winter¹, Raimond Wong², Anand Swaminath², Tom Chow¹
¹Medical Physics, Juravinski Cancer Center, Hamilton/CANADA
²Oncology, McMaster University, Hamilton/CANADA

Cyberknife® robotic radiosurgical treatment of liver employs an online motion management system to track and compensate for target motion during free-breathing. Lesion tracking on the Cyberknife is achieved using a room-mounted orthogonal x-ray system to localize internal fiducial markers as well as an optical camera system to measure the position of the patient’s abdomen during breathing. The system establishes a correlation model linking internal target position to an external optically-tracked surrogate to enable near-real-time robotic adjustments of the linear accelerator. However, inherent system delays (115 ms) require a prediction algorithm to estimate the future position. Throughout treatment, periodic x-ray images are collected to verify and update this internal-external correlation model.

In this study, our aim was to quantify key uncertainties in the targeting of liver lesions on the Cyberknife system. We analyzed the logged Cyberknife tracking information for a total of 28 patient treated over 124 fractions and isolated treatment images collected immediately prior to beam delivery. To assess target amplitude and absolute prediction errors, we isolated 20 s time intervals surrounding each treatment x-ray image. We computed target amplitudes using peak/valley detection and prediction errors using the absolute

SP079.5 - Deep Inspiration breath hold lung SBRT- Can Flattening Filter Free beam based VMAT combined with gated CBCT facilitate precise treatment delivery with sufficient dosimetric accuracy?

Author(s): Vallinayagam Shanmuga Subramanian¹, Vellian Subramani², Kaia Subramanian¹, Shanmugam Thirumalai Swamy¹, Murugesan Kathirvel³, Gandhi Arun³

Objective(s):The combination of VMAT technique using high dose rate FFF beams along with the computer controlled deep inspiration breath hold technique provides opportunity to further reduce treatment margins in lung SBRT over free breathing (FB) approaches. The aim of this study was to investigate the potential benefits of VMAT based DIBH SBRT over FB SBRT. This was performed by conducting a dosimetric comparison of VMAT technique with IMRT
technique using both DIBH & FB approaches.

**Materials/Methods:** Ten lung SBRT patients treated using 6MV FFF-VMAT based DIBH technique were retrospectively selected for this study. Treatment planning were performed in both DIBH & FB patient data set using IMRT & VMAT techniques. Treated patients dose prescription of 60 Gy in 5 fractions was used as standard dose prescription for the techniques. Plan evaluation was performed with RTOG0813 treatment planning criteria. Paired t test was used for statistical analysis. The dosimetric accuracy of the gated VMAT was assessed using a global gamma index (3% dose difference, 3mm DTA (Distance to agreement)) and measured with 2D detector attached to a solid cube phantom. Actual patients number of breath hold cycles and total delivery time with breath hold phases of 20/25s and recovery phases of 25 seconds were also incorporated during QA procedures.

Results: Irrespective of the techniques, DIBH approach could very well satisfy the RTOG0813 treatment planning criteria for the studied patients. As shown in table mean average Dose conformity of 1.03 + 0.012 for VMAT-DIBH was significantly better as compared with IMRT-FB, VMAT FB & IMRT-DIBH techniques (p<0.03). Mean average Lung V20Gy volume was 4.84+ 2.4, 5.22+ 2.5, 10.07+ 2.3, and 10.27+ 2.04% for VMAT-DIBH, IMRT-DIBH, VMAT-BH, and IMRT-BH respectively. In terms of Heart V15cc and Esophagus V5cc maximum dose, VMAT-DIBH plans exhibit the lowest as compared with the other techniques. Both the IMRT & VMAT-DIBH plans could be accurately delivered despite undergoing multiple beam on/off cycles, with mean QA pass rate over 95% (IMRT-DIBH VS VMAT-DIBH = Mean 96.42+1.2 vs 97.8 + 1.1).Treated DIBH patients gated CBCT analysis showed that average mean setup error was 2.8mm (range 1.5 - 4.2mm) in latero-lateral, 3.4mm (range 2.2 - 4.8mm) in antero-posterior, 3.2mm (range 2.4 - 5.6mm) in craniocaudal directions.

SP079.6 - Feasibility of markerless tumor tracking by sequential dual-energy fluoroscopy on a clinical tumor tracking system

Author(s): Jennifer Dhont, Kenneth Poels, Dirk Verellen, Koen Tournel, Thierry Gevaert, Femke Steenbeke, Mark De Riddler Radiotherapy, Universitair Ziekenhuis Brussel, Brussels/BELGIUM

The purpose was to evaluate the feasibility of markerless tumor tracking through the implementation of dual-energy imaging into the current clinical dynamic tracking workflow of the Vero SBRT system. An innovative approach of fast sequential fluoroscopy sequences was implemented omitting the pre-requisite of fast-switching kV-generators.

Two sequential 20s (11Hz) fluoroscopy sequences were acquired at the start of one fraction for 7 patients treated with DT on the Vero system. Sequences were acquired using 2 on-board kV imaging systems located at ±45° from the MV beam axis, at respectively 60kVp (3.2mAs) and 120kVp (2.0mAs). Table 1 shows the kV imager positions that were selected based on marker visibility. Prior to evaluation, the implanted fiducial was removed on all images to be evaluated, to not bias the results. Offline, a normalized cross-correlation algorithm was applied to anatomically match the high (HE) and low-energy (LE) images. Per breathing phase (inhale, exhale, maximum inhale and maximum exhale), the five best matching HE-LE couples were extracted for DE subtraction. A contrast analysis according to gross tumor volume (GTV) was conducted between the DE and HE images based on contrast to noise ratio (CNR). Improved tumor visibility was quantified using an improvement ratio (IR=CNRDE/CNRHE).

DE subtraction through sequential fluoroscopy was incorporated on the Vero system with only minor adjustments to the imaging settings. Removing the implanted fiducial was successful on all images. HE-LE sequence matching was effective for 12 of 14 imaging angles, correlation coefficients per imaging angle can be found in Table 1.

Table 1 Mean correlation coefficient per imager (Im) between high- (HE) and low-energy (LE) images, contrast-to-noise ratio (CNR) across tumor-volume for HE and dual-energy (DE) images, and relative improvement ratio (IR=CNRDE/CNRHE)

</table>

Overlying bony anatomy was removed on all DE images; Figure 2 shows an example. CNR per patient and per imaging angle can be found in Table 1. With the exception of two imaging angles, the DE images showed no significantly improved tumor visibility compared to HE images. Qualitatively, it was observed that for these imaging angles that showed no significantly improved CNR, the tumor tissue could not be reliably visualized on neither HE nor DE images due to a total or partial overlap with other soft tissue.

Dual-energy imaging by sequential fluoroscopy was shown feasible by implementing an additional fluoroscopy sequence into the DT workflow of the Vero system. However, for most imaging angles, DE images did not provide improved tumor visibility over single-energy images, most likely due to an overlap of the tumor with other soft-tissue. Optimizing imager settings and angles is likely to improve the efficacy of dual-energy imaging.

SP080.1 - Estimation of the second cancer risk from adjuvant radiation therapy for stage I seminoma of the testis

Author(s): Michalis Mazonakis¹, Theocharris Beriss¹, Charalambos Varveris², John Damilakis¹

¹Department Of Medical Physics, University of Crete, Heraklion/GREECE, ²Department Of Radiotherapy, University of Crete, Heraklion/GREECE

Purpose: To estimate the second cancer risk associated with the adjuvant radiation therapy for stage I seminoma of the testis.

Methods: The study population consisted of eleven patients with stage I testicular seminoma who underwent postoperative radiation therapy with a 6 MV photon beam. Three-dimensional conformal radiotherapy plans based on CT scans were generated for all patients. Two parallel-opposed anteroposterior and posteranterior fields were used to deliver 20 Gy to the para-aortic lymph node region. The organ equivalent dose (OED) to stomach, colon, liver, and pancreas, which were partly included within the treatment volume, was determined using differential dose-volume-histograms and a plateau dose-response model. Furthermore, a previously validated Monte Carlo model of a linear accelerator producing 6 MV X-rays was employed to calculate the radiation dose at sites excluded from the primarily irradiated area. Para-aortic irradiation to 20 Gy with standard treatment field sizes was simulated on a computational humanoid phantom representing an average adult man. Monte Carlo calculations were performed to determine the average radiation dose (Dav) received by each of the following out-of-field organs: brain, salivary glands, oral mucosa, thyroid, lung, esophagus, urinary bladder and prostate. The Dav and OED values together with organ-specific risk coefficients were used to estimate the excess absolute risk (EAR) of cancer induction at the age of 70 years due to radiotherapy of a typical 35-year-old patient.

Results: Monte Carlo simulations showed that the out-of-field organ dose from para-aortic irradiation varied from 0.004 Gy to 0.37 Gy. The mean OED value for stomach, colon, liver, and pancreas, as derived by the patient study, was equal to 2.50 Gy, 1.88 Gy, 1.43 Gy and 5.60 Gy, respectively. The organ-specific EAR for developing second cancer at sites outside the treatment volume was (0.002-0.9) per 10000 persons per year. The corresponding risk range for the partially in-field organs was (2.5-10.6) per 10000 persons per year. The highest EAR value was found for stomach cancer.

Conclusions: The risk of out-field cancer after adjuvant radiotherapy for stage I seminoma of the testis is low. However, the above treatment may lead to an increased probability for carcinogenesis at sites exposed to primary radiation. This elevated risk should be taken into account during the follow-up of testicular cancer survivors.

SP080.2 - 3D Slicer Gel Dosimetry Analysis: Validation of the Calibration Process

Author(s): Kevin M. Alexander¹, Csaba Pinter², Jennifer Andrea², Gabor Fichtinger², L John Schreiner³

¹Department Of Physics, Engineering Physics And Astronomy, Queen’s University, Kingston/ON/CANADA, ²School Of Computing, Queen’s University, Kingston/ON/CANADA, ³Department Of Medical Physics, Cancer Centre of Southeastern Ontario, Kingston/ON/CANADA

Advanced three-dimensional conformal radiation therapy techniques have rapidly developed in recent years. The techniques generate dose distributions with steep dose gradients to cover the tumor and spare healthy tissue, and these deliveries need validation. Three-dimensional dosimetry tools, such as gel dosimeters, have been shown to be promising tools for measurement and verification of radiation dose deliveries, particularly during commissioning of new treatment techniques.

Gel dosimetry consists of three-dimensional chemical systems that quantify the effects of radiation-induced chemical changes in a gelatin matrix which can be imaged using various systems, such as the Vista optical CT scanner (Modus Medical Devices, London, Canada). By its very 3D nature, gel dosimeters require extensive post-irradiation data processing. In our clinic, gel dosimeter analysis was traditionally performed using Matlab coupled with the Computational Environment for Radiotherapy Research and would take several hours to process and analyze data. To reduce analysis time and to produce a more robust analysis system, a gel dosimeter analysis workflow was developed using a custom extension in 3D Slicer (an open source and customizable computational tool used for image analysis and visualization). Gel dosimeter analysis using the extension now takes 5-10 minutes.

A major component of gel dosimetry analysis is the calibration relating the optical response of irradiated gel to dose. Here, we present a calibration method using measured depth dose data from well-characterized electron beams compared to optical depth dose data in an imaged gel. Four 1L jars from two batches of Fricke gel dosimeter were made and irradiated with 6x6 cm² beams using three different beam energies. To validate the robustness of the calibration component of the 3D Slicer extension, the calibration gel jars were analyzed five times and the mean sensitivity of each of the gels was determined. Consistency of measurements for a single user examining the four gel irradiations was shown to have high reproducibility, with a relative standard deviation of 0.1%. To examine the effect of inter-user variability of the gel calibration process, the analysis was performed by three different users. The mean sensitivities determined by the three users had a maximum relative standard deviation of 0.6%.

Overall, the calibration step of the 3D Slicer Gel Dosimetry Extension makes gel dosimeter analysis more consistent and about 20 times faster than previous dose readout approaches.

SP080.3 - Whole body interactive 3D visualisation of both the benefits and risks of radiotherapy for common cancers: a tool to guide decision making

Author(s): David Edmunds, Ellen Donovan
Joint Department Of Physics, The Royal Marsden Hospital, Sutton/UNITED KINGDOM

Purpose

More people who have had a common cancer are surviving. Radiotherapy is contributing to this success but it has long-term consequences. There is a complex relationship between the benefits of radiotherapy and the risks of adverse effects (e.g. cardiac damage or second cancer induction). These vary with many factors including disease stage, age at exposure to radiotherapy and radiation dose. The modern era of radiotherapy planning and delivery methods results in a wide variety of delivered dose to organs outside the treated region. Standard treatment planning systems calculate and display dose within the region of a planning scan. There is no tool describing doses beyond this region, or providing information on the benefits and risks of the radiotherapy based on plan specific doses and patient characteristics such as age.

We have developed the aRRESt (Radiotherapy Risk Evaluation System) program, which provides an interactive 3D visualisation of cardiac risks and second cancer risk estimates for radiosensitive organs throughout the body.

Method

A cross-platform graphical user interface (GUI) was developed using the C++ programming language, with 3D visualization and interaction provided by the Visualization Tool Kit (VTK) module. The GUI provides an indication of the lifetime risk of second cancer induction [1], and of major coronary event risk [2] for any treatment plan input. Dose cube and outlined regions of interest (ROI) are extracted from DICOM files exported from a commercial treatment planning system. Mean organ doses are used to estimate the lifetime/cardiac risks.

Figure 1

An image from the 3D interactive visualisation tool, which can be switched between dose and the risk of an adverse effect from radiotherapy for a selectable organ. The display shown is from a CT scan of an anthropomorphic phantom, extracted from the Pinnacle treatment planning system.

Conclusion

The aRRESt program provides a quick and convenient method of visualising the benefit-risk relationship for different radiotherapy treatment deliveries and patient characteristics. Currently based on a generic body model, the ultimate aim is to use patient specific information. The tool will be used in combination with the standard treatment plan to assist decision making on a per-patient basis.

SP080.4 - A Software App for Radiotherapy with In-situ Dose-painting using high Z nanoparticles

Author(s): Mohammed Jermoumi, Altundal Yucel, Yao Hao, Gizem Cifter, Erno Sajo, Wilfred Ngwa
Department Of Physics And Applied Physics, Medical Physics Program, University of Massachusetts, Lowell/UNITED STATES OF AMERICA

The purpose of this work is to develop a user friendly and free-to-download application software that can be employed for modeling Radiotherapy with In-situ Dose-painting (RAID) using high-Z nanoparticles (HZNPs). The RAID APP is software program written in Matlab (Mathworks, Natick, MA, USA) based on deterministic code developed to simulate the space-time intra-tumor HZNPs biodistribution within the tumor, and the corresponding dose enhancement in response to low dose rate (LDR) brachytherapy of I-125, Pd-102, Cs-131 and kilovoltage x-rays such as 50 keV and 100 keV. Through the graphical user interface (GUI) of the RAID APP, the user will be directed to different features to compute various parameters related to the dose enhancement and the biodistribution of NPs within high risk tumor sub-volumes. The software was developed as a tool for research purposes with potential for subsequent development to guide dose-painting treatment planning using radiosensitizers such as gold (Au) and platinum (Pt).

SP080.5 - Performing radiation therapy research using the open-source SlicerRT toolkit

Author(s): Csaba Pinter1, Andras Lasso2, An Wang3, Gregory C. Sharp4, Kevin M. Alexander4, David A. Jaffray4, Gabor Fichtinger2
1School Of Computing, Queen’s University, Kingston/CANADA, 2School Of Computing, Queen’s University, Kingston/CANADA, 3Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/CANADA, 4Radiation Oncology, Massachusetts General Hospital, Boston/UNITED STATES OF AMERICA, 5Department Of Physics, Engineering Physics And Astronomy, Queen’s University, Kingston/CANADA, 6Techna Institute, University Health Network, Toronto/CANADA

Purpose: Radiation therapy (RT) is a common treatment option for a wide variety of cancer types. Although we have seen significant improvements in this technique over the past years, performing research in RT is limited to using either expensive, closed, proprietary applications or heterogeneous sets of open-source software packages with limited scope, reliability, and user support. Our SlicerRT toolkit aspires to overcome these limitations by providing an extensive set of RT research tools leveraging the advanced visualization and image analysis features of its base platform 3D Slicer (see http://slicer.org).

Methods: The SlicerRT toolkit (see http://slicer.org) comprises of a set of 3D Slicer extensions: SlicerRT core [1], Matlab Bridge, Multi-dimensional Data, and Gel Dosimetry. The SlicerRT core extension contains 26 modules, many of which provide common RT tools used in most RT research scenarios. Numerous core modules
employ the advanced algorithms provided by the Plastimatch library [2]. Matlab Bridge provides a convenient way for connecting the researchers’ existing MATLAB algorithms to the SlicerRT ecosystem. Multi-dimensional Data offers a feature set for handling multi-dimensional datasets, such as longitudinal or 4D data. Finally, Gel Dosimetry [3] facilitates gel dosimetry analysis workflows through a streamlined, workflow-based end-user application. The toolkit is an open-source resource that is developed and maintained according to the highest standards in the industry, including flexible, maintainable architecture, automated testing, and the use of a software collaboration suite that enables accurate tracking of our efforts and plans.

Results: Four 3D Slicer extensions have been implemented, each of which can be downloaded from the 3D Slicer Extension Manager. Using these open-source software tools makes it possible to conduct cutting edge RT research without parallel development efforts. Essential RT tools are provided by SlicerRT core, augmented with the extensions Matlab Bridge and Multi-dimensional Data, supporting special use cases. Gel Dosimetry acts as a proof of concept for quick prototyping of advanced applications accommodating complex workflows. The user base of the toolkit is constantly expanding, with 30+ groups having adopted it so far. SlicerRT acts as a medium into which researchers can integrate their methods into, and which they can use to perform comparative validation, develop novel RT techniques, or transition advanced methods into routine clinical practice.

Future work: As SlicerRT has matured to contain most of the planned functions, our focus has shifted from feature development to usability and stability. Thus we propose to perform a complete overhaul of the current Contours mechanism to be more complete and more flexible. To enhance user experience, we plan to significantly improve our user documentation to make it as straightforward and helpful as possible. Also, although we have performed validation on core algorithms, it only covers a subset of the tools SlicerRT provides. It is also among our goals to validate the rest of the algorithms.

Acknowledgement: This work was in part funded by Cancer Care Ontario through Applied Cancer Research Unit and Research Chair in Cancer Imaging grants, and the Ontario Consortium for Adaptive Invention in Radiation Oncology (OCAIRO).

SP081 - Validation and Verification of Therapy Dose Delivery: Part 1

SP081.1 - Validation of Eclipse Treatment planning system Commissioning using Octavius 4D

Author(s): Paul B. Ravindran1, Aung Thaung2

1Department Of Radiation Oncology, The Brunei Cancer Center, Brunei/BRUNEI; 2Radiation Oncology, Pinlon Hospital, Yangon/ MAYANMAR

The accuracy of dose calculation in a treatment planning system mainly depends on the algorithm used for calculation, the beam data configured and the beam modelling in the treatment planning system. The Eclipse planning system uses the Analytical Anisotropic Algorithm (AAA) and the Acuros XB (AXB) for dose calculation and these have been extensively verified for its accuracy. The commissioning and quality assurance of a treatment planning system has been studied comprehensively ever since the computerised treatment planning system came in to use. Generally the validation of a TPS is limited to verification of point doses and dose profiles. The availability of the Octavius 4D enables a full 3D dose comparison.

Purpose: The purpose of this study was to validate the commissioning of Eclipse treatment system for photon beams of Clinac IX unit with Octavius 4D system that enables volumetric comparison of dose distribution.

Methods: Beam data configuration was performed on an Eclipse planning system (Version 13.0) for a Clinac IX dual energy linear accelerator with 6MV and 10 MV photon beams and six electron energies viz 6 MeV, 9MeV, 12 MeV, 15 MeV, 18 MeV and 22 MeV. The calculations for the validation were carried out with Analytical Anisotropic Algorithm (AAA) version 13 implemented in Eclipse planning system. Absolute point dose verifications were performed with 1D water phantom and 0.6 cc ion chamber supplied by PTW. The 729 detector array of the Octavius 4D system was used independently for 2D planar dose verification. The rotational unit of the Octavius 4D system with the inclinator and the 729 detector array was used for dose verification in 3D. Profile comparisons, 2D and 3D gamma analysis were performed to validate the Eclipse system for photon beam dose calculation.

Results: Good agreement was observed between the measured absolute point doses and the AAA calculated doses in water phantom. The agreement was within 2% and less than 1% at most points in the central axis. The 2D comparison of dose distributions pass rate for 3%/3mm gamma index criteria were 95% are above and the failed points were mostly in the penumbral region. The gamma analysis for 3D dose comparison also had pass rate of 96%-99% with 3%/3mm criteria for both 3D CRT and IMRT verifications.

Conclusions: The calculations performed by the Eclipse Treatment Planning system with the configured beam data and the Analytical Anisotropic Algorithm were accurate. The Octavius 4D system with the 729 detector array is a useful tool for comprehensive validation of the Treatment planning system for photon beams.
Evaluation of Electron Beam Algorithm of Prowess Panther Planning System for Customized cutouts of Different Sizes

Abstract: In this comparative study electron beam dose calculation algorithm used in prowess TPS is evaluated. This is done by comparing PDDs and OPFs (Output Factors) of different cutout sizes with minimum field size dimension of 2 cm for electron energies of 6 MeV, 9 MeV, 12 MeV, 15MeV, 21 MeV. Cutouts are designed in TPS and then fabricated in mould room using lipowitz. The measurement of PDDs and OPFs are carried out by using CC01 and Omnipro-Accept software in 3D water phantom and Dose 1 electrometer. The OPFs are measured at D max of each energy and cutout size. The calculated PDDs and OPFs from Prowess Panther are compared. OPFs and PDDs comparison were made for both SSD 100 cm and SSD 110 cm. The R20 – R90 region of PDD is selected for comparison with an increment of 10 points. Data analysis is carried out by calculating mean difference and standard deviation for PDDs and percentage difference for OPFs between measured and treatment planning calculations.

The values of mean difference between calculated and measured PDDs at 100cm SSD are less than 2mm for 2cm diameter circle up to 12 MeV. Higher than 12 MeV the values of mean difference are greater than 3 mm. Similar results are obtained with squares and rectangles of different sizes like 2cm square and 9x2 rectangle and the mean difference is less than 2mm for 6MeV, it increases with increase in energy. For cutout sizes having large dimensions from 3cm the agreement is within 2mm irrespective of cutout shape size and applicator size. Overall trend shows that with increase in energy mean difference increases although increase is more prominent for 2cm circle at 21MeV as compared to squares and rectangles at same energy. For extended SSD 110cm, the mean difference of depth doses follow the same trend as in case of standard SSD 100cm. In case of higher energies the calculated results are lower in upper part of the curve from R90 to R60 while in lower part the calculated values are higher. Calculated and Measured OPFs are also compared. OPFs are in good agreement for fields greater than 4 cm. But for fields smaller then 4cm disagreement is more than acceptable limits. The Planning algorithm over estimate dose in case of small field sizes as compared to measured results.

Prowess panther accuracy depends on field size and energy and slightly depends on field shaping. Accuracy of prowess panther does not agree well for field size which has any dimension as small as 4 cm, especially for low energies. Additional correction factors must be applied on MUs calculated from Prowess panther for field sizes smaller than 4cm.

Conclusion

The effectiveness of the MU calculation method was verified at SAGA-HIMAT. We are trying to put to practical use as soon as possible. Then the more efficient operation of the treatment beam would be possible.
Derived RBE\textsubscript{10} values based on the Microdosimetric Kinetic Model and SOI bridge microdosimetric spectra is presented in Fig. 2. The RBE\textsubscript{10} values match very well with those obtained from the TEPC measurements. Due to the high spatial resolution of the microdosimeter, more detailed RBE\textsubscript{10} measurements were obtained at the end of the SOBP compared to the TEPC. It should be noted that the bridge microdosimeter measurements were done in a PMMA phantom while the TEPC measurements were carried out in water.

This work presented the first RBE\textsubscript{10} derivation in a $^{12}$C ion therapeutic beam using a high spatial resolution SOI microdosimeter and demonstrated a simple and fast method for Quality Assurance in charge particle therapy using silicon microdosimeter.
SP081.5 - Characterization of a ZnSe(Te) inorganic scintillator for scintillation dosimetry applications

Author(s): Patricia Duguay-Drouin¹, Sam Beddar², Luc Beaulieu¹
¹Radio-oncologie Et Axe Oncologie Du Centre De Recherche Du Chu De Québec, CHU de Québec, Québec/CANADA, ²University of Texas MD Anderson Cancer Center, Houston/TX/UNITED STATES OF AMERICA

Purpose: The purpose of this work is to characterize a ZnSe(Te) inorganic scintillator for future application in scintillation dosimetry. This study will determine the usability of this scintillator within a multipoint scintillation detector system.

Methods: Different lengths of a ZnSe(Te) scintillator (MolTech GmbH) ranging from 0.5 to 3.0 mm were tested and optically coupled to a 15 m optical fiber (ESKA GH-4001). The photodetectors used in this study are a spectrometer (QE65Pro, Ocean Optics) and a photomultiplier tube (H10721, Hamamatsu). The detector was irradiated using an orthovoltage device (Xstrahl 200) at 120, 180 and 220 kVp, and a linear accelerator (Varian Clinac iX) at 6 and 23 MV for photons beams and at 6, 12 and 18 MeV for electrons beams. The energy, particle type, dose and dose rate dependencies were examined. Also, the attenuation within the scintillator was measured and its emission spectrum was characterized under various irradiation conditions.

Results: The scintillator demonstrates energy and particle type dependence for both the light production and spectral shape. The ZnSe(Te) measured spectrum ranges from 550 to 800 nm for beam energies listed above. For electron beams and MV photon beams, a component at 690 nm is added and the peak at 771 nm is shown to increase with energy (fig. 1). For a given energy, linear dose dependence is observed for all beams tested (R²>0.996). Moreover, the scintillator exhibits no dose rate dependence for MV photon beams tested. However, at 120 kVp, a dose rate dependence obeying a power function (R²=0.998) is observed (fig. 2).

Figure 1: Spectra for different energy beams

Figure 2: Dose rate dependence for 120kVp, 6MV and 23MV

Conclusion: The ZnSe(Te) inorganic scintillator has been characterized for dosimetry applications. When using this scintillator, one must takes into account the dose rate, energy and particle type dependences. Despite these dependencies, this scintillator with a spectrum of higher wavelength remains a good candidate for multi-point applications.

SP081.6 - Determination of correction factors for the use of ionization chambers in the presence of magnetic fields

Author(s): Gabriel O. Sawakuchi, Geoffrey S. Ibbott, Michelle V.P. Mathis
Radiation Physics, The University of Texas MD Anderson Cancer Center, Houston/UNITED STATES OF AMERICA

Various groups in Europe, North America and Australia are currently developing magnetic resonance imaging (MRI) guided radiotherapy technology by integrating an MRI scanner to a linac (MRI-linac). MRI-guided radiotherapy will provide exquisite images of soft-tissue with high temporal resolution to allow tracking tumor and organ motions in real-time. One of the challenges to implement MRI-linac technology in clinical practice is to calibrate the radiation output under the presence of a strong magnetic field (B-field). The addition of the permanent B-field from the MRI affects the response of ionization chambers (ICs) (Meijssing et al. 2009, Phys. Med. Biol. 54 2993-3002; Smit et al. 2013, Phys. Med. Biol. 58 5945-57; Reynolds et al. 2013, Med. Phys. 40 042102). In this work we show preliminary results of Monte Carlo (MC) calculations of beam quality correction factors under the presence of a B-field for various ICs. We used the Geant4 toolkit throughout this work. First we established the best set of parameters for the Geant4 condensed history algorithm so that the code passes the Fano test within 0.5% (Poon et al. 2005, Phys. Med. Biol. 50 681-94). Then, we used well-established methods from the literature (Muir and Rogers 2010, Med. Phys. 37 5939-50) to calculate kQ values for several ICs in a SL25 6 MV beam without (kQ) and with (kQB=1.5T) the presence of a 1.5 T B-field. The maximum percentage difference between our kQ values and TG-51 (McEwen et al. 2014, Med. Phys. 41 041501) results for a set of seven chambers was 1.4%, demonstrating that our MC model is adequate (Table 1). Our results in Table 1 show that kQB=1.5T values strongly depend on IC model/geometry and material composition of the ICs, i.e., for identical geometry but different collector and wall materials, kQB=1.5T values were different. For the set of ICs
investigated we observed corrections of up to 4.4% for the Exradin A19 chamber. Among the investigated chambers, the PTW 30011 presented the smallest correction factor (1.2%). Our future work will use a realistic energy spectrum of an MRI-linac unit (Atlantic, Elekta Inc.) to calculate $k_{QB}=1.5T$ values for selected ICs. Future work is also needed to validate calculated $k_{QB}=1.5T$ values against experimental data.

Table 1: $k_Q$ values calculated using Geant4 with and without the presence of a 1.5 T B-field. The B-field was perpendicular to the beam and perpendicular to the axis of the cylindrical ICs.

SP082 - Nonlinear Dynamic Analysis

SP082.1 - Aging Process: Central Pressure Waveform Loss of Complexity

Author(s): Ricardo L. Armentano1, Leandro J. Cymberknop2, Walter E. Legnani1, Manuel R. Alfonso3, Franco M. Pessana1
1School Of Advanced Studies In Engineering Sciences, National Technological University, Ciudad Autónoma de Buenos Aires/ARGENTINA, 2Buenos Aires Regional Faculty, National Technological University, Ciudad Autónoma de Buenos Aires/ARGENTINA, 3Faculty Of Engineering And Exact And Natural Sciences, Favaloro University, Ciudad Autónoma de Buenos Aires/ARGENTINA

Introduction: Aging is defined as the age-related decline in physiological function where arterial stiffening and hypertension constitute related disorders in the cardiovascular system. Age can be considered as one of the most powerful determinants of cardiovascular risk, usually viewed as a chronological, unmodifiable and even untreatable factor. Arterial mechanical properties of the small vessels are known to be altered with advancing age (dilatation and stiffening), leading to a rise in pulse pressure (PP). In this sense, central pulse pressure (cPP) has been more closely related to cardiovascular events than peripheral pulse pressure (pPP). From the point of view of chaos theory, multiscale and nonlinear complexity (structure and interactions of individual subsystems) appears to degrade with aging and disease. In our previous studies, waveform complexity of arterial pressure (AP) was related to stiffness variations as well as to the presence of wave reflection. Additionally, age related changes were also analyzed in cPP waveform. Objective: The aim of the present study was to evaluate changes in the waveform complexity of cPP as a result of the aging process. Material and Methods: Continuous, noninvasive blood pressure measurements were analyzed in 16 healthy subjects (8 young, 20-29 yr and 8 aged, 50-69 yr). Individuals with cardiovascular disease risk factors were excluded from the experiment. A generalized transfer function was used to obtain the cPP waveform from the pPP (measured by applanation tonometry) using a customized software (SphygmoCor, AtCor Medical, Sydney, Australia). Time series waveform complexity was assessed by means of fractal dimension (FD) calculation, based on the method provided by Higuchi. Statistical analysis was carried out using an unpaired Student’s t-test. A value of p<0.05 was considered statistically significant. Results: A significant decrease in FD values was obtained in cPP waveform for aged subjects (1.09±0.02 to 1.04±0.01), concomitant to a cPP increase. Conclusion: Considering previous studies, the loss of complexity has been hypothesized to be an indicator of the transition from normal aging to frailty. In the present work, loss of waveform complexity was observed as a consequence of the aging process in cPP. Arterial structural changes were reflected in FD variations, independently of the AP calibration, due to the space filling property and the fine structure of the waveform were analyzed. Further studies are necessary in order to determine if changes in waveform complexity can be utilized as a complementary factor of vascular aging.

SP082.2 - Changes in COP scaling behaviour in quiet stance after mTBI

Author(s): Coren Walters-Stewart, Andre Longtin, Heidi Sveistrup
University of Ottawa, Ottawa/CANADA

The analysis of centre of pressure (COP) timeseries is well suited to the evaluation of balance control. Balance control is often interpreted as a physiological control system with coordinating sensory inputs and muscle outputs. COP variables can provide clues about the controlling mechanisms affecting balance. Mild traumatic brain injury (mTBI) often results in functional impairments including balance impairments that seem to suggest altered signalling within the brain. It was hypothesized that the altered mechanisms affecting balance after mTBI might be reflected in altered scaling properties of COP. University football players (n=74) were tested at the beginning of the season as a baseline and were retested if they sustained an mTBI during the season (n=6, tested an average of 15.7±7.2 days after injury). Players who did not sustain an mTBI were also retested at the end of the season for comparison (n=17). Each participant was asked to stand quietly with eyes closed for 90 seconds on a portable force platform. Scaling behaviour was determined by (1) classifying the timeseries using the beta estimate, (2) identifying how many scaling regions exist, and (3) calculating scaling estimates for each region. Data for mTBI and uninjured groups were compared to their own respective baselines. Results demonstrated that while typical scaling behaviour of COP timeseries were always the same—short-term persistence (H1>0.5) and long-term anti-persistence (H2<0.5)—the group who had sustained mTBIs demonstrated a significant change (between baseline and post-mTBI) toward less random short-term values in the mediolateral direction whereas the uninjured players did not (see Figure 1). While the overall ability to maintain balance is not altered, demonstrated by the unchanging long-term scaling behaviour and by the fact that no players were falling over, some subtle changes to how the COP is being controlled in balance do occur after an mTBI. This method of measuring changes to balance may be useful in determining whether or not players are being returned-to-play when still impaired in ways that may lead to re-injury.

SP082.3 - Tracking algorithm of spiral wave core in a cardiac tissue using Hilbert transform and phase variance analysis

Author(s): Naoki Tomii1, Masatoshi Yamazaki2, Haruo Honjo2, Ichiro Sakuma1
1The University of Tokyo, Tokyo/JAPAN, 2Nagoya university, Nagoya/JAPAN

Arrhythmia is a common and increasing disease, especially in developed countries. There are several treatment approaches toward arrhythmia such as anti-arrhythmic drug, radio frequency ablation and electrical stimulation. To investigate about mechanism of arrhythmia and improve efficacy of these treatments, optical mapping system has been used in many previous works. Optical mapping is an useful measurement system of cardiac excitation. This mapping system is mainly composed of isolated heart dyed with voltage sensitive dye, high brightness excitation light, and high speed camera. Because emitted spectrum of voltage sensitive dye changes with a change of transmembrane potential of each cardiac cell, we can measure the activation potential at each points and it’s propagation as the change of fluorescence spectrum. Using this system, propagation of excitation in cardiac tissue can be measured in high speed (more than1000 fps) and in high resolution (less than 0.05 mm / pixel).
Spiral wave propagation of excitation in a cardiac tissue (spiral reentry) is known to play a key role to cause and sustain dangerous arrhythmia, such as tachycardia and fibrillation both in ventricular and atrium. It has been reported that stability of the center of spiral wave (spiral core) is related to the sustainability of spiral reentry. Thus detection and tracking of spiral core in optical mapping images is important to analyze spiral reentry. Bray et al. proposed phase analysis of spiral reentry using Hilbert transform. In this method, core of spiral is mathematically defined as “phase singularity point” around which the contour integration of phase value is 2π or -2π. However, applying this definition to detect the spiral core in optical mapping images is difficult because there are huge amount of surrounding counters in an image. In this work, we present novel detection algorithm of the core of spiral reentry in optical mapping images. Using angular dispersion of phase values in a bounding box, we detected high dispersion point as the core of spiral. We will report the accuracy of the detection and the computational cost of this algorithm.

**SP082.4 - Mapping the Fractal Dimension of Arterial Pressure**

**Author(s):** Leandro J. Cymberknop, Ricardo L. Armentano, Franco M. Pessana, Manuel R. Alfonso, Walter E. Legnani

**Institution:** Buenes Aires Regional Faculty, National Technological University, Ciudad Autónoma de Buenos Aires/ARGENTINA, Faculty Of Engineering And Exact And Natural Sciences, Favaloro University, Ciudad Autónoma de Buenos Aires/ARGENTINA, School Of Advanced Studies In Engineering Sciences, National Technological University, Ciudad Autónoma de Buenos Aires/ARGENTINA

**Introduction:** The cardiovascular system is constituted by a complex network of vessels, where highly uniform hierarchical branching structures, that cover a wide range of diameter scales, are regulated by the anatomy and local flow requirements. In recent years, homeodynamic and holistic concepts such as fractal and nonlinear analyses were proposed to be helpful to study the complexity of physiological functions. In the systemic circulation, arteries bifurcate many times before they become capillaries where the scaling factor of vessel length, diameter and angle between two children branches is established at each level of recurrence. For these reason, this type of vascular system can be described using a fractal scaling principle. In this sense, it was observed than the basic pattern of blood distribution is also fractal, imposed both by the anatomy of the vascular tree and the local regulation of vascular tone. In our previous studies, arterial pressure time series (AP) waveform complexity changes were evaluated by means of a fractal dimension (FD) measure. To our knowledge, a holistic analysis of FD variations throughout the arterial network has not been previously reported. **Objective:** The aim of the present study was evaluate the variation of arterial pressure waveform complexity considering its anatomical location in the branching structure. **Material and Methods:** Continuous, AP measurements were obtained in the following sites: left ventricle and descending thoracic aorta (five male mongrel dogs, instrumented with solid-state implantable pressure sensors, Konigsberg Inc., Passadena, USA) and carotid and femoral arteries (five male middle-aged subjects, without cardiovascular risks factors, evaluated by applanation tonometry, Millar Inc., Houston, USA). Due to experimental limitations, invasive (in humans) measuring methodologies were performed. Assessment of FD in AP time series waveforms was developed by applying Higuchi’s method. Topological dimension was not considered in FD relative changes (ΔFD) calculation. Statistical analysis was carried out using the paired Student’s t-test. A value of p<0.05 was considered statistically significant. **Results:** A significant increase in ΔFD was observed at the thoracic aorta (higher complexity) in respect to ventricular pressure FD values (+233.06±75.34%). On the other hand, femoral artery AP manifested a decrease in ΔFD (lower complexity) in comparison to the carotid site (-56.51±13.62%). **Conclusion:** A holistic evaluation of AP waveform complexity in the arterial network was performed, where its FD changes were related to the vascular site. While the ventricular pressure time series was observed to be “fractalized” at the aortic level (due to the waveform is more exposed to the multiple wave reflections), AP showed a loss of complexity at distant sites from the cardiac muscle, manifesting an ‘unwrinkling’ phenomenon.

**SP082.5 - Moving deterred fluctuation analysis for inspecting time evolution of scale invariant structures in biomedical signals**

**Author(s):** Hamidreza Saghir, Tom Chau, Azadeh Kushki

**Institution:** Ibbme, University of Toronto, Toronto/Canada

Detrended fluctuation analysis (DFA) is commonly used for characterizing the fractal structure of biomedical signals. One of the underlying assumptions of DFA is that the fractal structure is consistent [AK1] in time and can be characterized by a single scaling exponent. However, the scale invariant structures of multifractal signals are modulated in time and lead to the existence of a spectrum of scaling exponents. Conventionally, Multifractal analysis has been used to study the statistical distribution of a range of scaling exponents. However, these methodologies do not provide any information about the time evolution of scaling exponents.

This article introduces a new methodology based on DFA, called moving deterred fluctuation analysis (MDFA) for examining the evolving scale-invariant structure of a signal in time through phase-couplings between temporal scales. Instead of using non-overlapping time intervals as in conventional DFA, MDFA computes the root mean square of the detrended residuals in a moving window at each time point. This approach allows to analyze the coupling between different time scales and to identify the evolution of the scaling properties of the signal. The results show that MDFA allows to detect the presence of scale-invariant structures in biomedical signals and to monitor the evolution of their scaling properties over time.

We used MDFA to inspect time evolution of scaling exponents in ECG signals during a movie-watching task in group of 33 participants (n=33, age: 12.5 +/- 2.9 years, full-scale IQ: 112.9 +/- 14.1, 19 male[AK2]). The results show that the modularity of the local scaling structure was significantly influenced by condition (i.e. relaxed, stroop practice, anxious, p<0.04). This modulation was not significantly different for a white noise series of the same length. MDFA returns an average scaling exponent of 0.5 [AK3] for white noise which is consistent with the results of other methods. These results suggest that MDFA is a useful tool for inspecting the time evolution of scale-invariant structures in multi-fractal signals and should be further investigated.
figure 1. Example of MDFA for one participant (left) compared to white noise (right). Top panel demonstrates the time modulation of scaling exponents. Middle panel shows the evolution of root mean square residuals across time and scales. Bottom panel shows the probability distribution of scaling exponents in anxious (stroop) and relaxed (baseline) conditions. (practice is a transitory state in which the participant practices the task a few times before starting the stroop task)
"When can I drive?" is a question frequently asked of orthopedic surgeons following injury and surgery of the lower limb. Surgeons are left to make a difficult decision, as there are no specific guidelines on when patients should be cleared to drive, and there are significant discrepancies between mean recovery times for different procedures in the literature. Although there is no clear consensus between law enforcement, insurers, road authorities and the medical community, the decision as to whether an orthopedic patient can adequately brake an automobile following surgery is generally defaulted to the surgeon. Surgeons are faced with the dilemma of managing their duty to the patient, to the public, and the medicolegal risks involved with giving patients advice on when they can get back on the road. Studies suggest that a simulator may be useful in assessing braking capacity following surgery of the lower limb; however, they are currently not widely used by surgeons. Significant recurring issues exist with current or proposed simulators: (1) they generally cannot be used to assess trauma patients due to the need for baseline testing preoperatively, (2) limited data is available to demonstrate their ability to evaluate a patient's braking performance, (3) braking forces are not translated into stopping distances or indeed not considered at all, (4) and the devices are often not practical in an outpatient setting. In order to drive safely, one must be capable of stopping a vehicle in an emergency. Braking capacity depends on a host of patient variables including visual acuity, neurological function, musculoskeletal function, and the influence of drugs among others. Our intention is to develop a method to evaluate performance of the lower limb, specifically. This work presents the design of a simulation device that will provide surgeons with an objective assessment of their patient's braking performance in an outpatient clinic. This simulator will compare calculated total stopping distances after the appearance of an emergency stimulus with the total stopping distance recommended for specific driving speeds in the literature. Alternatively, this maximum stopping distances will be inferred using recommended brake reaction times and forces to provide a benchmark for the assessment of braking performance.

Objective. The main objective of this research is to compare the impedance parameters between knees with and without meniscal injury in female athletes.

Materials and methods.

a) Volunteers. In this study participated 6 sportswomen (Age: 19.5±0.8 years, BMI: 20.4±3 kg/m²). Previously, all volunteers were assessed for meniscal problems comparing right and left knees by a sports medical professional staff. All volunteers had physical condition according to the parameters of the American College of Sports Medicine. Body composition were measured to all volunteers.

b) Procedure. The bio impedance parameters where assessed with a BIOPAC System (MP150), which injects an electrical current of 1 mA at different frequencies (12.5 kHz, 25 kHz, 50 kHz, 100 kHz).

In order to monitor the knee condition by bio-impedance, four electrodes were placed in each knee. All volunteers were asked to fully extend each leg in periods of 5 seconds to perform the test at 30 seconds.

c) Signal processing. All the data were analyzed using the Matlab software. The impedance data were analyzed and compared at different impedance frequencies. Subsequently, these results were correlated with the clinical findings made to all the volunteers.

d) Statistical analysis. The comparison of impedance parameters between knees with and without meniscal injuries were made using a t-test for independent groups.

Results. All the volunteers had meniscal injury in the right knee; however there were not statistical differences when we compare the length of the lower pelvic limb the mean and standard deviation (X±SD), were: 91.9±7.4 vs. 91.8±7.0, for right and left limbs (t=0.02, p=0.98). The mean and standard deviation of the bio impedance parameters were as follows: 48.9±10.7 vs. 71.5±19.1. When we compare with a t-test we found significant differences between knees.
ABSTRACTS | IUPESM 2015 WORLD CONGRESS ON MEDICAL PHYSICS & BIOMEDICAL ENGINEERING

with and without injury (t=−3.58, p=0.002), see figure 1.

![Figure 1. Differences in the mean and SD of impedance parameters of right and left knee with and without meniscal injuries, t=-3.58, p=0.002.](image)

**Conclusions.** In this study we demonstrated that the impedance technique could be a good option in order to monitor the knee condition.

**SP083.4 - Development and evaluation of a mechanical stance controlled orthotic knee joint with stance flexion utilizing a timing based control strategy flexion**

**Author(s):** Hankyu Lee1, Matthew J. Leineweber2, Jan Andrysek2

1Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, 2Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto/CANADA

Medical conditions such as spinal cord injury, spina bifida poliomyelitis and others can result in severe loss of lower limb muscle function and lead to impairments in mobility. For patients who have the potential to walk, orthotic treatments including knee-ankle-foot-orthosis are commonly used to address problems with knee instability. Recent advancements have led to the development of more sophisticated orthotic knees that restrict knee flexion during stance-phase while allowing articulation during the swing-phase. These stance-control orthotic knee joints stabilize the knee joint during the stance-phase of gait without restricting swing-phase flexion, thus achieving a more normal gait for individuals with quadriceps muscle weakness. However, there are inherent challenges in ensuring safe weight-bearing capabilities while allowing for maximum knee flexion during swing-phase over a range of walking speeds. **The work here presents a new type of stance control strategy and stance controller design employing a mechanical timing system, which was modelled using empirical data and functionally tested in a gait laboratory.**

Pilot clinical testing was performed on a prototype stance-control orthotic knee joint incorporating a novel timing system for controlling knee lock during swing- and stance-phase. Our timing-based control strategy was developed using empirical models of gait cycles at normal and fast walking speeds. Clinical feasibility of this approach was tested on a poliomyelitis patient using spatiotemporal, kinematic, and kinetic gait data captured using a standard motion capture system and floor-mounted force plates. Walking trials were performed with the orthotic in its unlocked functional mode, as well as in a locked mode to represent traditional knee-ankle-foot-orthoses.

The results of these tests showed that our prototype design provided reliable knee stability while facilitating swing-phase flexion, for more normal knee joint kinematics in both the swing and stance phases. In particular 44 degrees of swing-phase flexion and 15 degrees of stance-phase flexion were achieved, compared to 5 degrees stance-flexion in the locked conditions. Our empirical stance-control model indicates that the timer can range from 0.572 to 0.963 seconds while allowing for successful operation for both normal and fast walking speeds. During clinical evaluation, all trials were completed with the subject being able to consistently unlock the knee during walking without incidence of instability when the knee would not unlock.

**The stance control mechanism was effective for gait initiation, steady state walking and gait termination, however further testing is needed in-situ to assess other mobility conditions.** Critical to the reliability and robustness of the proposed strategy, was the requirement of the chosen triggering conditions to be sufficiently independent of variations in walking speed. Our analysis shows that a large enough window exists for which a single timer duration would ensure the timely locking of the knee joint, to ensure both swing-phase initiation and proper locking throughout stance-phase. In addition to providing stance control and stance flexion, the knee joint design was significantly decreased size and weight from current stance-controlled orthotics.
SP084 - New Designing Ideas

SP084.1 - Soprano - Nasogastric Tube Insertion Guide

Author(s): Karthik Kannan1, Sum Kok Meng2, Foad Kabinejadi3, Hwa Liang Leo1

1Department Of Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE, 2Singapore General Hospital, singapore/SINGAPORE, 3Department Of Surgery, National University of Singapore, Singapore/SINGAPORE

Nasogastric Tubes (NGTs) are used for feeding and administering oral medication in patients with either impaired swallowing mechanisms or obstruction in the upper aero digestive tract that prevents oral feeding. They are inserted through the nose into the stomach and represent an important means of long-term feeding especially in patients with neurological diseases (e.g. strokes). In the US alone, 1.2 million NGTs are inserted yearly. NGT placement entails a significant risk of malpositioning that may result in death from aspiration of liquids into the lungs and expose healthcare institutions to significant medicolegal liability risks. Yet, current methods of confirming correct placement are not foolproof. Moreover ensuring proper placement consumes significant resources- e.g. Chest x-rays for confirmation, hospitalization for costly alternative endoscopic and radiological guided placement methods.

Our device, Soprano is coined on the concept of frugal engineering. With a simple, elegant and innovative solution, we addressed a clinical problem that demands immediate attention and possibly save numerous lives and millions of dollars. Our basic specifications were easy steerability and an accurate and reliable feedback mechanism to identify the correct placement of NGT in the esophagus. (1) Our device is a semi-rigid guide that has a specific elliptical cross-sectional profile that acts as a funnel through which the NGT can be passed through easily into the esophagus and thereby all the way into the stomach. (2) The guide has been specifically designed with an inherent curvature conforming to the anatomy of the nasopharynx area that enables easy steering. (3) Additionally, the guide provides an accurate audio feedback that works on the basis of our inherent inhalation and exhalation cycles. This produces an audio feedback should the guide be wrongly inserted into the trachea. However, no sound is produced if the guide is correctly inserted in the esophagus. Further research into human physiology and sound frequency produced within the esophagus would allow us to further improve Soprano to accurately detect the frequency of sound produced when correctly placed in the esophagus, giving a positive signal instead of the current negative confirmation. (4) The NGT can then be passed through the guide and the guide later removed via a special slit and having a perforated guide. Soprano promises to be a simple, cost and time-effective solution that for both patients and healthcare professionals alike.

SP084.2 - High Output Impedance Current-Conveyor Oscillator for Electrical Bioimpedance Applications

Author(s): Pedro Bertemes-Filho1, Volney C. Vincence1, Dejan Krizaj2

1Electrical Engineering, Universidade do Estado de Santa Catarina, Joinville/BRAZIL, 2Laboratory For Bioelectromagnetics, University of Ljubljana, Faculty of Electrical Engineering, Ljubljana/SLOVENIA

The objective of this work is to investigate the use of a current conveyor oscillator with current output for tissue excitation in a wide frequency range. It was implemented using a sinusoidal oscillator that provides an output current in a wide frequency range with a maximum amplitude of 650 μApp. It uses a second generation class AB current conveyor developed with CMOS AMS-0.35 μm technology and is configured in a Wien bridge structure. It has a low power oscillator supplied by ±1.5 V with a consumption of approximately 400 μW. The simulation results showed a frequency sweep between 1.04 to 1,230 kHz by using an integrated bank of capacitors. The maximum total harmonic distortion was 1.8% in the frequency range. The output impedance was bigger than 46 MΩ at lower frequencies but 2.4 MΩ at 1 MHz. The development of a low power current source without using an external voltage generator might be very attractive for measuring cell impedance at the electrode site and for designing battery powered bioimpedance systems.

SP084.3 - Healthcare Device for People Affected by Dementia

Author(s): Sara M. Velez, L. V. Wilches

Mechatronics Engineering, Escuela de Ingenieria de Antioquia, Envigado/COLOMBIA

Dementia may be defined as a progressive disorder that affect cognitive abilities in a level enough to cause disability to face everyday life [1]. Around 44 million of people worldwide suffer Dementia and it is expected that this number will reach until 75 million to 2030. Almost 60% of them live in countries without high incomes and have a weak public health service. Although the term Dementia refers to a group of illness that can produce similar symptoms, the Alzheimer’s disease is the main of them in terms of patients affected. The symptoms can be devastating because of they include a total memory loss and the lack of recognize familiar objects, remember and perform basic activities. In addition, changes in personality and the necessity of professional assistance affect not only the patients but also their families and friends [2, 3].

At least 25% of the hospitalized patients in clinical services have dementia, and many of these admissions could be prevented if their relatives provide a better support at home [4]. Although this condition implies a save of significant health resources, there are risks related to an inadequate healthcare of patients affected by Dementia outside of a hospital. In this way, the first problem to solve is their technical support.

Technical support can be defined as one device that aims to monitor, assist, prevent, or alleviate a disability without losses in the quality of life of the patients that require it. As a response of this necessity, it has developed a device to allow the technical support of the patients with Dementia, without direct vigilance from their caregivers. The device is a bracelet that reminds the users about his or her daily activities through easy recognition signals. A tracking system that uses sensors in limited areas provides information about the patient’s location. In addition, a record system allow regulation of medicines, activities and other relevant information about patients in real time. This device provide autonomy and independence when the Dementia is in its early or middle stage.

The main features of this device are their low cost, easy construction and simple functioning compared to other options available in the market. These differences allow to extend its use in countries with emerging economies without significant investments. In addition, its use could help to relieve the saturation of health services and save resources in different medical assistance levels.

It is a technical difficulty to acquire large field image under the complexity and cost restrictions of diagnostic and instant field research purpose. The goal of developing our wide field-of-view imaging system is to achieve tolerable resolution to detect fluorescently-labeled micro-sized particles or cells in the entire image field without the field curvature effect, while maintaining a cost-effective procedure and simple design. In order to obtain a large field image with a simple lens-based optical imaging system, we designed a curved sample chamber. We conducted a systematic study including optical simulations and experiments with a curved sample substrate to ensure a simple and practical design of the proposed system, aimed for a clearer and wider large field of view on a flat plane image sensor. In order to apply our system to point-of-care CD4 test, which can monitor HIV/AIDS disease progression by counting absolute number of CD4 T-cells in a known volume of the blood, the curved sample chambers were manufactured by an injection molding technique. The curved sample chamber reduces the field curvature and image distortion at acceptable level for the CD4 test without using a sophisticated optical elements. The optimal design has a field-of-view of 13 mm and a magnification factor of 0.54. The designed system enables us to image the objects at a spatial resolution > 8 µm and it can be also used for dynamic measurements, such as microscale flow dynamics and micro-organism behavior, by time-lapse imaging and particle tracking methods. Potential applications include a point-of-care medical diagnosis as well as a rapid environment monitoring in field study.
New technological capabilities (such as multi-core processors with hypervisors) are enabling medical devices to execute a much wider range of functions than has been historically possible. Next generation medical devices will be able to support or perform a wide range of process control functions and business functions that augment their value beyond the core clinical functions. “Intelligent” medical devices will be able to identify themselves on the network, support heightened security safeguards, do periodic self-tests and status reports, support remote diagnosis and repairs, issue predictive failure alerts, perform essential functions autonomously offline, enforce safety “guardrail” precautions against user error, and interface automatically with service and asset management processes to enable real-time updates, configuration management, and performance monitoring.

Four major stages of interoperability maturity are proposed, with specific functions assigned to each stage and sub-stage. (1) Network Transaction management, (2) Peripherals management, (3a) Availability and Change Mgt, (3b) Reliability, Risk Mgt, (3c) Configuration Mgt, (3d) System Lifecycle Mgt, (4) Integrated Clinical Environment (ICE, ASTM 2761). Key functions are identified that will enable more rigorous standardization of data and process models.
SP085 - Women in Medical Physics

SP085.1 - Women in medical physics: Current status Results from IOMP survey
Author(s): Virginia Tsapakis
Konstantopoulio General Hospital, Athens/GREECE

Introduction: The gender composition of medical physicist (MP) workforce around the world is principally unidentified. Acknowledging this issue, IOMP decided to perform a survey to investigate the percentage of women MPs in different countries as compared to total MPs. It was expected that the survey would provide information on gender imbalance, if it existed, and provide a basis for establishment of a subcommittee. Moreover, the results of the survey could provide an opportunity for countries as well as IOMP, for a more in-depth analysis and deliberate on further actions.

Materials and Methods: An online questionnaire was created, prepared as a Google Forms survey asking the country, the total number of MPs, the number of women MPs and finally the gender of the person providing the data. The questionnaire was sent to all 6 regional member organizations of IOMP and a major country, the USA. The regional organizations were asked to distribute it among national member organizations (NMOs) and even to non-IOMP member countries.

Results: Sixty-six countries responded to the survey. The results cover more than 3/4 of the MP manpower in the world. The total number of MPs was 17024, of which 28 % were women (4807). The median values of percentages of women were 21 % in the USA, 35 % in Asia, 33 % in Africa and 24 % in Latin America. It was noted that a substantial number of European countries were far away from the target that the European Commission has set, that is 40 %. On the other hand, there were countries in other regions of the world such as the Middle East and Asia, in which women MPs outnumbered men MP. Interestingly enough, there were countries where only women MPs existed and all these were developing countries.

Conclusion: This is the first international survey ever that investigated the gender situation on MPs around the world. Due to these very interesting findings, IOMP decided to perform a more in-depth study in the very near future.

SP085.2 - Is there a ‘Leaky Pipeline’ for Women in Clinical Medical Physics in Canada?
Author(s): Leigh Conroy1, Elizabeth Watt1, Wendy L. Smith2
1Department Of Medical Physics, Tom Baker Cancer Centre, Calgary/AB/CANADA, 2Department Of Oncology, University of Calgary, Calgary/AB/CANADA

We examined the role of women in clinical medical physics in Canada through a representative career path. Gender data for centers affiliated with the Commission on Accreditation of Medical Physics Education Programs (CAMPEP)-accredited residencies and graduate programs were found through departmental websites and informal surveys. Historical certification data was obtained from the Canadian Organization of Medical Physicists (COMP).

Canadian medical physicists receive certification of competence through Canadian College of Physicists in Medicine (CCPM) examinations. Members (MCCPM) must have a minimum level of work experience and fellows (FCCPM) must have additional work experience and significant contributions in the field. A cross-sectional view of the proportion of women at each career stage is shown in Figure 1.

We hypothesized that the paucity of women with FCCPM certification could be due to the natural time delay between career stages. Figure 2 shows the historic trends of the number of CCPM members in total (members and fellows) and fellows separated by gender.
fewer women in leadership positions. This may change in time as the increasing number of women entering the field advance through their careers.

**SP085.3 - Women in Medical field in Brazil: gender equality?**

**Author(s):** Lidia V. De Sá, Simone K. Renha  
Medical Physics Department, NATIONAL NUCLEAR ENERGY COMMISSION, RIO DE JANEIRO/BRAZIL

The women participation in the Brazilian workforce has increased greatly since 1970; however, it is still lower than men in many specialized professions. In 2013, for a population around 200 million people, the female birth rate was 49.3%. Despite that, at the age of vocational training (20 to 25 years old) this percentage reverses to 50.4%, reaching 53.8% for women older than 60 years, retirement age. In order to verify the presence of women in the medical field a study was carried out including physicians, nurses and medical physicists based on the Brazilian Health System and professionals associations records. The results showed that for physicians there is already gender equality among professionals, presenting an increase from 37% to 52% in ten years for female professionals. For nursing, approximately 80% are women, showing the predominance of this gender due mainly to the characteristics of “caretakers” of this profession. For medical physics area, the scenario is not the same. The country has a reasonable number of certified medical physicists (MP) in radiotherapy, 273, considering that there are 275 linear accelerators, 68 cobalt equipment, 86 high dose rate (HDR) and 61 low dose rate (LDR) brachytherapy devices in use. However, only 36% of these professionals are women. In nuclear medicine, there are in total only thirty certified MPs while only 30% of them are female with the appropriated skill to attend the demand that currently comprises 814 SPECTs, 110 PETs devices and more than 3000 therapy procedures. Diagnostic radiology presents an even more critical situation, with sixty nine certified MPs for a large number of devices, around 3648 CTs, 22052 X-rays, 4250 mammography units, among others practices, where only 36% are women. In conclusion it can be observed that the women representation in scientific and technical workforce is growing fast in the last decade. However, for medical physics field, the women representative in the medical physics area is not expressive and has not been increasing at the same rate of the others medical professionals. Significant efforts should be made on professional formation, emphasizing the female MP education.

**SP085.4 - Women Biomedical Engineers as Consultants in Clinical Engineering Field in Latin American Countries: Case of Study**

**Author(s):** Gabriela Jimenez Moyao, Carmen Rendon Isguerra, Sandra Galan, Claudia D.C. Cárdenas Alanis, Erendira Jimenez, Maria Fernanda Zumpano Romero, Stefany Penafort Flores, Paola Salgado Rodriguez, Pamela Lopez Uroz  
Escala Biomedica, Mexico City/MEXICO

The Consultancy in the engineering field has been a common practice since many years ago; the Biomedical Engineering is not an exception; the multidisciplinary of the career gives the biomedical engineers a wider perspective in the clinical practice, infrastructure planning, management, logistics and engineering fields and the analytical results of this convergence promotes the problem solving and high accuracy advices. Women Biomedical Engineers in the consultancy field are a growing hired staff in Mexico and a specific case of study is a clinical engineering consultancy company in Mexico City with projects mostly in Mexico and Latin America, whose staff is mainly formed by women.

The objective of this article is to define the consultancy model inside and outside the company describing how the women inside the company have been educated based on an inspirational leadership, mostly since the school by the company’s founder experience about the clinical engineering field and the motivation to follow values such as truth and justice and also to develop skills such as leadership, effective communication, strategic thinking, innovation and creativity and a systematic improving of their technical knowledge in order to be creative in the problem solving in the consultancy field.

Furthermore, outside the company, describing the challenges women have faced during the consultancy work in the different work fields with different stakeholders such as Hospital Staff, Planning Hospitals Teams, Medical Equipment Vendors, how it has been faced and the solutions and the contribution of these experiences to positioning the company and the women staff members in a competitive mostly men labour field.

In the article there is reference to the interviewed women and also there are mentioned significant testimonies that confirm the hypothesis about the huge impact of the women consultancy work in the clinical engineering field within work teams in the healthcare sector. As a conclusion the experiences described suggest that the women biomedical engineers with leadership skills and good technical knowledge are valuable for the improvement of the healthcare sector and the impact is huge when the knowledge is share inside different organizations through the consultancy efforts.
For the indirect effects of radiation, our results show that both hydroxyl radicals and hydrated electrons are responsible for the enhanced formation of damage in modified DNA. In the presence of Pt-adducts, hydroxyl radicals mainly contribute to the formation of single-strand break, while hydrated electrons are the main species responsible for the DSB formation.

In conclusion, Pt-drug modification is an extremely efficient means of enhancing the formation of DNA DSBs by both LEEs and hydrated electrons created by ionizing radiation.

The aim of this work is to investigate the effects of different sizes and concentrations of gold nanoparticles (GNPs) on the cell viability in both lymphoma and choroidal melanoma cells. To this end, GNPs were synthesized following the Fern’s method in three sizes of 20, 40 and 60 nm. Both Melanoma and Lymphoma cells were grown in 6 (24-well) plates so that the first three plates containing Melanoma cells and the last three plates containing Lymphoma cells. In all six plates, the first five wells were coated with five different concentrations of GNPs and the sixth of them was assigned as control. For both Melanoma and Lymphoma cells, one plate was injected by GNPs with the diameter of 20 nm in five different concentrations of 200, 150, 100, 50 and 25 µg and two plates were injected by GNPs with the concentrations of 600, 400, 200, 100 and 50 in which the nanoparticles have a diameter of 40 nm in one of them and 60 nm in another. MTT method was used to assay the cell viability after incubating the cells for 48 hours at 37°C. Compared to the control, in all six plates the results show that both melanoma and lymphoma cells grown were decreased in the present of nanoparticles. However, there was difference on cell grown between Melanoma-GNPs and Lymphoma-GNPs exposures in vitro. For instance, at the concentration of 200 µg the present GNPs in Lymphoma cells showed strong decrease of cell viability, while, the viability decrease in melanoma cells was not very considerable. Choose of the size and concentration of GNPs to achieve the best results in ophthalmic brachytherapy are depend on the tumor. Considering the sensitive tissue which the eye is involved in, the dose to normal tissues in comparison with the resultant dose increase in the tumor is of utmost importance in investigation of GNPs effects on ophthalmic brachytherapy dosimetry which require In-Vivo study. Also, further in vitro cytotoxicity tests are required before high-concentration GNPs can be used for choroidal melanoma treatment.

The main focus of the present study is to investigate dose enhancement effects in presence of gold nanoparticles (AuNPs) in proton delivery site of the ocular melanoma by the use of fixed pencil beam method associated with the Harvard ocular nozzle in a series of Monte Carlo simulations. Moreover, this paper also aims to present a comparison of the obtained results between the actual eye model, consisting of all sections of the eye and realistic compositions in the presence of AuNPs, and in the exact same organ, albeit in a preclinical experiment of the mentioned material. Previous Monte-Carlo simulations have strained to acquire the same results obtained through latest experiments that have considered dose enhancement effects of proton treatments with existence of AuNPs, but to no avail; thus, multiple simulation codes such as MCNP, GEANT4, and FLUKA have been taken into account to insure the least possible deviation from in vivo findings. Rigorous libraries and models have been used, and all physical processes involved have been accounted for; furthermore, for the sake of accuracy, the production of the most probable secondary particles due to interactions with matter has also been examined. Contribution to dose enhancement effects are due to stopping losses, coulomb interactions, and elastic and non-elastic collisions of proton itself, as well as from secondary particles that are produced in mentioned processes. The attempt of such paper is to shed light on the endless possibilities of escalating the efficiency of medical endeavors through interdisciplinary methods which combine various aspects of science and technology to attain desired results.

The objective of this work is to develop a method that allows generating a calibration curve for the DNA DSB focus assay in-vitro after internal irradiation with radionuclides. The samples should be exposed to radionuclides used in radionuclide therapy, nowadays also called molecular radiotherapy (MRT), simulating absorbed doses and dose-rates that are similar to the ones that have been observed in patients.

Therefore, we studied the induction of radiation-induced co-localized γ-H2AX and 53BP1 foci in lymphocytes as surrogate markers for the DNA DSB focus assay in-vitro absorbed doses to the blood for the two most frequently used radionuclides in MRT (I-131 and Lu-177).

Methods: We investigated blood samples of 3 healthy blood-donors. 9 experiments were carried out (2 experiments with I-131 and 1 with Lu-177 for each volunteer). For each experiment we withdrew approximately 28ml of blood at different time-points. One sample without radioactivity was used to determine the individual background focus rate. Radionuclides of known activities were diluted with NaCl and mixed with whole blood (3.5ml) to result in radioactive blood samples with different nuclide concentrations to deliver absorbed dose rates between 5mGy/h and 100mGy/h. Each vial was incubated for 1h at 37°C on a roller-mixer to uniformly blend the samples during the exposure. Thereafter, white blood cells were recovered by density centrifugation and washed in PBS followed by fixation in 70% ethanol. Samples were subjected to two-colour immunofluorescence staining and the average frequencies of the DNA DSB focus assay will provide additional information for in-vivo absorbed doses to the blood per nuclear disintegrations occurring in 1ml of blood were calculated for both isotopes using the radiotherapy transport code MCNPx2.71.

Results: Overall 55 blood samples were evaluated in a dose range between 6mGy and 95mGy. Only minor nuclide-specific, intra- and inter-subject deviations were observed. We obtained a linear relationship between the number of DSB-marking γ-H2AX and 53BP1 foci/nucleus and the absorbed dose to the blood (R²=0.92) which agrees well with published values for external irradiation.

Conclusions: This in-vitro calibration method for the DNA double strand break focus assay will provide additional information for in-vivo measurements in patients after molecular radiotherapy and will further improve the absorbed dose to the blood calculation method.
SP087 - Educational and Professional Activities: Part 2

PRESIDENTS CALL

SP087.1 - The potential role of IFMBE in improving the state of medical equipment in developing countries

**Author(s):** Anna Worm¹, Andrei Linnenbank²

¹Tropical Health and Education Trust, London/UNITED KINGDOM, ²Electrical Engineering, Mathematics And Computer Science, Delft University of Technology, Delft/NETHERLANDS

In developing countries medical equipment is often non-functional. Well known reasons for that are donations of already broken equipment and lack of spare parts and consumables. It is to be expected that current state of the art medical equipment is even less suitable for donation, given the way they are designed to function under conditions that are hard to find in rural areas in low resource countries. The key to start solving these problems lies in improving technical education at all levels in these countries. This paper explores how the IFMBE can work together with several other institutions (WHO, local professional organizations, non-profit organizations, Ministries of Health and Education,...) to train and sustain a competent technical workforce that can do maintenance, repair, and design of biomedical equipment using locally available materials and knowledge.

SP087.2 - Biomedical Engineering Education through Outreach Programs in Hospitals

**Author(s):** Franco Simini¹, Fernando Leon Moloney¹, Jorge De Giobbe²

¹Núcleo De Ingeniería Biomédica, Universidad de la República, Montevideo/URUGUAY, ²Rio Negro, Hospital ASSE, Fray Bentos/URUGUAY

Health expenditure is a measure of the share of activity related to health care, both preventive and curative. Industrialized Countries spend around 10% of Gross Domestic Product (GDP) [1] with a high 17.9% for the USA. Middle income Countries, such as Uruguay, have lower figures, but growing as does the dissemination of medical actions in larger portions of the population. More hospitals are build and more equipment are installed every year. Traditional Engineering Education is slow at developing Biomedical Engineering (BME) Programs, because initial demand is scarce and because existing Electrical or Mechanical Engineers usually take over specific functions after some training by equipment providers. Uruguay has a 120 years old University but is only starting to train BME graduates. Job offers greatly exceed qualified staff available, which led us to suggest urgent training programs based on an Outreach Program in Hospitals (OPH), therefore at low cost.

OPH based BME training is build upon existing Electrical Engineering and Systems Engineering Programs, using courses of maths, physics, chemistry, software development, electrical engineering and management. Six optional courses are added, from electronic design to medical image processing and management (DICOM, PACS), electrical safety standards, medical terminology, physiology and anatomy.

A full year design project of a biomedical equipment is assigned to groups of three students, to both foster collaborative attitude and to obtain a functional solution to a clinical instrumentation problem.

Students are then assigned in their fourth University year to a full time six months intern-ship in a Secondary Level Hospitals, where
BME is non-existent. This is done within a University Outreach Program. As the only technological reference persons in the Hospital Director’s office, BME students face a variety of maintenance, purchasing, staff training, safety measures enforcement, documentation and installation/removal of equipment. Every student is assigned a remote instructor who acts as a reference available on call or otherwise. The instructors are University teachers in capital city Montevideo, while students are in remote (100 Km to 600 Km) hospitals, where a basic “intern-ship” salary is paid, in addition to feeding/lodging on premises.

Results of this low budget, OPH based BME program are promising with first graduations expected June 2015. The main results are (1) self confidence and sense of responsibility acquired by student (2) its low cost and (3) the interest of BME firms for future employment.

From the Hospital Point of view, equipment documentation, staff safety instruction and maintenance purveyors relations are the benefits so far.

This model of integrated, easily implemented BME Program based on University Outreach has the potential to be considered in other settings in Latin America, the Caribbean and elsewhere, where quick BME staffing requirements must be met at low cost, helping to reduce Health Expenditure.

SP087.3 - Clinical Engineer: a health professional to recognize
Author(s):

Background:
In latter years, Clinical Engineer’s figure is taking on more and more importance in health technology management, due to his technical knowledge and capacity to interact with different fields professionals. Unfortunately, this situation does not reflect reality; in many low and medium income countries this figure does not exist and in many high income countries Clinical Engineer is not recognized as health professional, but very often compared as biomedical technician. Internationally Clinical Engineers, as subset of Biomedical Engineers, belong to Unit Group 2149 “Engineering Professionals Not Elsewhere Classified” under the International Standard Classification of Occupations produced by the International Labour Organization.

Objective:
Clinical Engineers community is strictly collaborating with World Health Organization (WHO), in particular with Adriana Velazquez Berumen, Senior Adviser on Medical Devices, to recognize Clinical and Biomedical Engineer’s figure worldwide.
The main aim is to stress the importance of Clinical Engineer in healthcare facilities. This work will be a chapter of Human Resources for Medical Devices, part of WHO Medical device technical series.

Methods:
The approach used in this work analyses the main activities carried out by Clinical Engineer, in order to give awareness of all activities involving this figure. Therefore the analysis focuses on Clinical Engineer’s role at national level, in particular within the Ministries of Health of different Countries. This analysis was possible through several statements by professionals who work at national level. Finally the analysis gives attention to Clinical Engineering’s diffusion worldwide in the six WHO regions (African Region, Region of Americas, Eastern Mediterranean Region, European Region, South-East Asia Region, Western Pacific Region) through data from Clinical Engineering Societies around the world.

Conclusions:
Clinical Engineer is without doubt a professional who needs to be recognized worldwide with more support. He is a fundamental resource in health technologies management and contributes both to healthcare organization and patient health.

SP087.4 - “Rehabilitation Engineering: Designing for Ability” - A summer outreach course for attracting talented high school students to the rehabilitation engineering field
Author(s): Vicki Komisar1, Emily C. King2, Eve Moore3, Sabah Hassan4, Aaron Marquis5, Justin Chee6, Rosalie H. Wang7, Sunita Mathur8, Tilak Dutta2, Cesar Marquez-Chin2
1Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, 2Department Of Mechanical And Industrial Engineering, University of Toronto, Toronto/CANADA, 3Handy-Metrics Corporation, Toronto/CANADA, 4Central Neighborhood House, Toronto/CANADA, 5Toronto Rehabilitation Institute - University Health Network, Toronto/CANADA, 6Rehabilitation Sciences Institute, University of Toronto, Toronto/CANADA, 7Department Of Occupational Sciences And Occupational Therapy, University of Toronto, Toronto/CANADA, 8Department Of Physical Therapy, University of Toronto, Toronto/CANADA

Motivation:
We need to inspire talented students to pursue rehabilitation engineering, and develop the technologies that will help our aging population overcome disabilities and live fulfilling lives for as long as possible. Our team experiences a perennial challenge of attracting top-quality students to important yet often unglamorous facets of this field (e.g. supporting independent toileting for people with mobility challenges), partly because prospective students may not recognize these challenges, or see how they can be addressed through science and engineering. In response, we developed a week-long course in rehabilitation engineering for high-school students through the University of Toronto’s “Da Vinci Engineering Enrichment Program”, which we have led every summer since 2012.

Course structure:
The course was designed provide students with memorable interactive experiences in a range of rehabilitation engineering applications. To discover accessibility challenges, students completed a “Built Environment Obstacle Course”, where they navigated UofT while simulating mobility and vision deficits, then assessed how built environment features affected their experience. Students participated in hands-on demonstrations in Toronto Rehab’s Challenging Environment Assessment Laboratories and Neural Engineering Lab to understand how engineering technologies are being applied to problems such as preserving hand dexterity in cold weather, and allowing people who are ‘locked-in’ to control their own environments. Guest speakers included engineers, clinicians and an entrepreneur who could communicate authentically to the students about the challenges, importance and rewards of developing and commercializing technologies to improve the lives of people with disabilities. The week culminated with a “Home-Care Design Challenge”, focused on solving problems related to aging-in-place. These design problems were selected from real client case studies presented by a home-care field educator.

Student feedback:
Students reported significant improvements in their understanding of key learning objectives (Figure 1). Students appreciated the Toronto Rehab visits, the diverse topics, the design challenges, and the instructional team’s ability to make the content understandable, interactive, and relevant.

The degree has been designed in such a way that student internship
is seen to be the first of its kind in Sub-Saharan Africa. It has been
running for less than three years with some other institutions in the
country offering Diplomas.

The degree has been designed in such a way that student internship
is an integrated part of the training where the students are actually
graded for their performance. This was brought about to improve
the awareness of the Biomedical Engineers and students in hos-
pitals as well as companies where they were otherwise unknown.
Internship posts have been secured in all government hospitals
and many private hospitals and companies. Companies Such as
SinoAfrica Uganda, Joint Medical Stores have continuously offered
placements for the students. The students are given clear objectives
with specific outcomes from each placement. They get a place-
ment supervisor as well as an academic supervisor to monitor their
progress.

The Uganda Industrial Research Institute (UIRI) has gone a step
further in supporting the degree programme. They not only provide
placements for the students but also over dedicated training such as
embedded systems and programming that students can take to
improve their knowledge and skills.

The awareness of the Biomedical Engineers and students in hos-

Expected outcomes: All of the participating students gained an
awareness of the problems faced by older adults and the societal
importance of finding solutions. Those who pursue engineering will
better understand their potential roles in rehabilitation engineering
and the importance of including stakeholder perspectives. Con-
versely, those who pursue other medical disciplines will appreciate
the importance of engineering in medicine and the potential for col-
laboration with engineers to advance their work.

The process for developing the proposed curriculum was performed
by structuring the types of knowledge needed for risk management
on HIT obtained through the exploration and study of the environ-
ment in which these technologies are embedded. The exploration of
the literature and specific standards to manage IT risks pointed out
several incidents involving the use of HIT. It was also investigated
the types of risks associated with the use of HIT, the professional
characteristics of IT professionals and the necessary requirements
to apply the standards for risk management on the healthcare sys-
tem. This investigation has shown the kind of knowledge required
by the CE professionals. The proposal curriculum to train clinical
engineers for managing HIT are shown at Table 1.

SP087.7 - A Successful High School Science Mentorship Program: Students on the Beamlines at the Canadian Light Source

Author(s): Tracy Walker¹, Tomasz W. Wysokinski¹, Mark A. Webb¹, Ning Zhu¹, George Belev¹, Cécilia Barrette-Leduc², Katarina Stefanovic², Lylia Xiao², Sara Marrè², Shu Yi Zhai², Yu Xin Zhuang², Marie-Eve Brassard², Denise Miller³

¹Bmit, Canadian Light Source Inc., Saskatoon/CANADA, ²Pensionnat Saint-Nom-de-Marie, Montreal/CANADA

Canada’s only synchrotron is an extremely brilliant source of X-ray and infrared light for research in a multitude of disciplines. We also have a unique program that engages high school students in authentic science research experiences. The Students on the Beamlines (SotB) [1] program connects high school students from across Canada with scientists at the Canadian Light Source (CLS) for mentorship through an authentic science research experience. “Authentic” indicates that we facilitate a research project that is as close to what professional scientists do as a high school student is capable. These are not demonstration experiments. Students must design a project that builds on previous work (through literature review) and ask a scientific question that requires synchrotron techniques to address. The results of their experiment are expected to potentially produce novel information that is of interest to the scientific community. It is this negotiation between the goals of producing ‘good science’ and creating an ‘educational and learning experience’ that is part of what makes this program unique. Key to the program is that the students function as primary investigators. Their mentors facilitate, direct and advise the students, but the project belongs to them and they make the decisions.

The case study presented is one from Pensionnat Saint-Nom-de-Marie, a girls’ school in Montreal, Canada. Honey bees in Canada are suffering significant winter death due to infestations of the Nosema fungus. It is known that the infestation deforms the digestive system of infected bees. Students used the Biomedical Imaging & Therapy (BMIT) beamline at CLS to collect x-ray projection and CT images of healthy and infected bees clearly showing the bees’ digestive system.

More than 500 students have participated in SotB so far and report that the experience has had a profound impact on their view of research, careers in science and of scientists. Teachers are eager to involve their students because the program fits with current educational initiatives encouraging student engagement through the use of inquiry methods in the science classroom. Several other synchrotron research facilities are emulating the program. The point of this presentation is to share our experience so the concept of student participation in mentored authentic science research can spread. In our case, using a synchrotron is the context and a hook to attract student participation. Any research context would work similarly.

SP088 - Computer Aided Diagnosis

SP088.1 - Automatic Analysis of Plantar Foot Thermal Images in at-Risk Type II Diabetes by Using an Infrared Camera

**Author(s):** Luis Vilchahuan*, Rachid Harba*, Raphael Canals*, Martha Zequera*, Carlos Wilches*, M.T. Arista*, L. Torres*, H. Arbanil1
1Biomedical Engineering, PUCP, Lima/PERU, 2Prisme, University of Orleans, Orleans/FRANCE, 3Electronic Department, School Of Engineering, Pontificia Universidad Javeriana, Bogota/COLOMBIA

Temperature of the plantar foot surface is an important feature in type II diabetes as abnormal temperature variations can be an early sign of foot diseases. In this paper, automatic way to analyze these temperature variations is presented by using an infrared camera. A robust acquisition protocol is proposed and an image processing software is developed. Three types of analysis are performed. First, the mean plantar foot temperature of both feet results from a segmentation procedure based on the Chan and Vese active contour method. Second, the point-to-point absolute mean difference between the 2 feet is assessed by using a rigid registration method. Third, significant hyperthermia regions such that the point-to-point absolute difference is greater than 2.2°C are highlighted. All these measures are fully automatic and do not need manual intervention. 32 type II diabetic subjects in a pre-ulcerative state were recruited in the Dos de Mayo hospital (HNDM) in Lima, Peru. These persons were classified in two risk groups of developing an ulcer based on a medical exam: a medium risk group, and a high risk group. Results show that the mean temperature of the plantar foot surface is higher of 1°C in the high risk group compared to the medium risk group. The mean point-to-point absolute difference shows identical values in the 2 groups. Finally, 9 subjects out of the 82 ones show significant hyperthermia of one foot compared to the other (6 in the medium risk group and 3 in the high risk group). It is expected that the new opportunity to automatically analyze foot temperature in hospitals or in diabetic health centers will help in reducing foot ulcer occurrence for type II diabetic persons.

SP088.2 - Computer Assisted Diagnosis of Sclerotic Bone Lesions from Dual Energy CT

**Author(s):** Duc Fehr1, Charles R. Schmitzlein1, Sinchun Hwang2, Joseph O. Deasy1, Harini Veeraraghavan2
1Memorial Sloan Kettering Cancer Center, New York/UNITED STATES OF AMERICA, 2Radiology, Memorial Sloan Kettering Cancer Center, New York/UNITED STATES OF AMERICA

**Purpose:** To develop a computer assisted diagnosis (CAD) tool for the detection of sclerotic bone lesions in the pelvic region from dual energy computed tomography (DECT). Automatically identifying every single bone metastatic lesions from CT images is difficult owing to (a) large number of such lesions, and (b) very low contrast between the lesions and the marrow or bone.

**Method:** We developed a CAD tool that automatically detects sclerotic bone metastases from DECT images from the pelvic region. Our method consists of two stages. In the first stage, the bone and marrow regions are automatically segmented through a voxel-wise classification of the DECT image represented as a composition of multiple materials by using support vector machine classifier, followed by morphological smoothing. The appropriate material composition is determined through a learning using SVM that selects the best material composition for segmenting the bone and marrow from the rest of the image. In the second stage, the contrast inside the bone and marrow regions are enhanced through bi-histogram equalization followed by mean shift clustering. Mean shift clustering groups voxels with similar intensities into single clusters. Finally, the segmented regions extracted from the mean shift clusters are scored by the their shape. The following parameters including area, eccentricity, solidity, major axis, minor axis, perimeter, and the medial axis are used as constraints on the shape. Shape filtering prefers isolated regions that are solid, with small elongation and smaller size rather than highly elongated shapes (such as the bones). The shape filtering outputs potential sclerotic bone lesion regions, which can then be validated by a radiologist.

**Results:** We compared the candidate regions generated by our method with the ground truth regions manually identified by a radiologist. Our results agreed with the radiologist marked regions despite the presence of confounding metal artifacts and the low contrast between healthy bone and the lesions.

**Conclusions:** We developed a CAD tool that automatically detects sclerotic bone lesions in the pelvic areas from dual energy CT. The detected lesions using our approach highly similar to the radiologist identified regions despite the presence of confounding structures with similar intensities including the sclerotic lesions, healthy bone and metal artifacts.

SP088.3 - Mutual Information Based Template Matching Method for the Computer Aided Diagnosis of Alzheimer Disease

**Author(s):** Esra Polat, Albert Guvenis
Institute Of Biomedical Engineering, Bogazici University, Istanbul/TURKEY

**Background**
Early and reliable detection of Alzheimer Disease (AD) from Positron Emission Tomography images using computerized methods is a desirable objective for the effective management of that disease. Several characteristics of the computer aided diagnostic system (CAD) are important for improving this process: (1) Taking advantage of the growing number of images in databases (2) Ability to search a database for similar cases (3) Robustness with respect to data acquisition and processing factors (4) Full automation. In particular the third and fourth requirements are important in view of the fact that many CAD systems require user intervention.
Purpose

Our goal was to develop a fully automated CAD system for detecting AD that can meet these requirements.

Method and Materials

We have used the Alzheimer’s disease Neuroimaging Initiative (ADNI) database for this study. Images for each patient were co-registered in order to correct for patient motion and had voxel sizes of 160 x 160 x 96. Voxel size was 1.5x1.5x1.5 in mm. There was 397 PET images including 259 normal and 138 AD patients.

A similarity measure based on mutual information (MI) was used to determine the closest matches for a new case. A K-Nearest Neighbor algorithm based distance measure was used to decide if a new image was from a healthy or AD patient. A leave one out evaluation method was implemented. Evaluation results were computed using ROC analysis. All development was carried out in a Matlab environment.

Results

Initial ROC analysis resulted an area under the curve (AUC) equal to 0.744±0.025 for this dataset. Much higher AUC values are expected for the nonlinearly registered images across patients. This is work in progress.

Conclusions

First results show that it is possible to discriminate between AD and healthy individuals by using template matching and mutual information as a similarity metric. Further studies are underway in order to improve these results by introducing nonlinear registration methods and by adjusting the image size and grey scale parameters used in the process. Robustness, adaptation ability to growing databases without having to retrain the system and case based reasoning possibilities will be some advantages of the new CAD system.

Figure 1 ROC Curve for the first database of images
also had imaging prior to fracture. An expert Radiation Therapist manually contoured the residual bone within the fractured vertebral body. A system based on Clarion Technology Inc’s “Spinemapper” application that automatically identifies vertebral levels and segments vertebral bodies, previously applied in unfractured vertebral bodies was extended to automatically contour the volume of each fractured vertebral body. The automatic method produced volumes highly correlated ($R^2=0.994$) with, but approximately 9% less than the expert contoured volumes. Using a curve fit to the volumes of adjacent “normal” vertebrae, the percentage change in volume in the fractured vertebra was estimated. Based on such curve fits, the estimated percentage volume loss ranged from 5% to 40% in the patient group studied. For the three subjects where both pre- and post-fracture CTs were available, the post-fracture assessment of predicted percentage volume loss matched the measured value based on pre- and post fracture data within 10%. This study demonstrates the viability and precision of this method to automate the analysis of fractured vertebral body volume and height reduction. These factors can then be incorporated into the scoring and management of patients with vertebral fractures.

Fractured Vertebral Body Volumes: Automatic vs Manual Segmentation

**SP089 - Tissue Modelling**

**SP089.1 - The protective effect of the eyelid on ocular injuries in blunt trauma**

*Author(s):* Xiaoyu Liu$^1$, Lizhen Wang$^2$, Jing Ji$^2$, Yubo Fan$^3$

$^1$School of Biological Science and Medical Engineering, Beihang University, Beijing/CHINA, $^2$School of Biological Science and Medical Engineering, Key Laboratory for Biomechanics and Mechanobiology of Ministry of Education, National Key Lab of Virtual Reality Technology, Beihang University, Beijing/CHINA, $^3$National Research Center for Rehabilitation Technical Aids, Beijing/CHINA

The instinctive blink reflex makes the eyelid close when a foreign body is approaching the eye. This study aimed to investigate the protective effect of eyelid on ocular injuries in blunt trauma. A finite element model of the eyelid model was created and was incorporated into a validated eye model. The process of a projectile impacting on a naked eye and an eyelid-covered eye were reproduced in dynamic simulation. Dynamic responses on the cornea and retina were performed to evaluate the risk of damage to the tissues. The simulation indicated that the eyelid significantly protected the cornea against damage from blunt impact, especially for a small-size projectile. This is because the eyelid distributes the local stress concentration to the whole ocular surface. However, the eyelid failed to provide the retina with an effective protection against damage in blunt trauma. This is because the retinal damage is a typical contre-coup injury, which is the result of shockwave propagation in the eyeball. In conclusion, the eyelid has different protective effects on ocular injuries caused by different injury mechanisms for eye closure.

**SP089.2 - A Tale of Two Tendons: The Tradeoff between Strength and Fatigue Resistance**

*Author(s):* Samuel P. Veres, Tyler W. Herod, Neil C. Chambers

Saint Mary’s University, Halifax/CANADA

Two predominant, functional classes of tendons exist: energy storing tendons and positional tendons. Energy storing tendons operate under much greater in vivo stresses than positional tendons, and are more prone to injury. Using a bovine forelimb model, we assessed the ultrastructural differences between superficial digital flexor (SDF, energy storing) and common digital extensor (CDE, positional) tendons. Scanning electron microscopy was used to study the ultrastructures of 4 SDF/CDE tendon pairs from 4 different animals at magnifications up to 90,000X. SDF tendons were found to have significantly smaller diameter collagen fibrils than CDE tendons (77.3±26.6 vs. 134.9±51.7 nm; $p<0.0001$). The collagen fibrils in SDF tendons were often bundled together by a dense network of filamentous webbing that ran predominantly perpendicular to fibrils’ longitudinal axis. Similar webbing was not observed in the CDE tendons. Hydrothermal isometric tension analysis of intermolecular collagen crosslinking, conducted using 7 SDF/CDE pairs from 7 different animals, showed that the energy storing SDF tendons had significantly more crosslinking (denaturation temperature: 65.2±1.1 vs. 62.9±1.1°C; $p = 0.0003$), and significantly more thermally stable crosslinking (portion of samples that survived the temperature ramp to 90°C: 85.7% vs. 0%; $p = 0.0006$) than the paired, positional CDE tendons. Thermal assessment using differential scanning calorimetry confirmed SDF and CDE tendons to have markedly different collagen crosslinking. Samples from paired SDF and CDE tendons had significantly different onset temperature (64.2±0.7 vs. 63.1±1.0°C; $p=0.0035$), endotherm full-width-at-half-maximum...
INTRODUCTION

Insoles and customized footwear are used to alter the plantar pressure (PP) distribution during gait. However, so far, it is not possible to predict the effect of these interventions on PP. This would undoubtedly enhance the customization process. The aim of this study is to evaluate a newly developed contact model, which allows to calculate dynamically the PP within a multibody gait simulation framework.

METHODS

Standard gait analysis was performed on 10 healthy subjects (mean age 62.2±4.6 years, mean BMI 24.6±2.2 kg/m²). The experimental setup included a 6 cameras BTS stereophotogrammetric system (60Hz), synchronized with 2 Bertec force plates (960Hz) and 2 PP systems (Imagortesi, 150Hz).

The PP simulation is performed during a moment-driven forward analysis using the experimental 3D kinematics and ground reaction forces in combination with a scaled generic musculoskeletal model as input in OpenSim. A scattered bed of spring-damper systems [1] was used as contact surface attached to the calcaneus of the model, which was obtained from a CT-scan of a healthy subject.

An optimization procedure optimized the contact parameters and geometry position based on the experimental ground reaction force. The performance of the contact model is evaluated by comparing the simulated and measured peak pressure curves (fig. 1).

RESULTS

A good agreement between simulated and measured peak pressure was found for all regions (see Fig. 1). In the first part of stance (30-60%) the overlap was nearly maximal, while around 80% of the gait cycle the overlap was lower. The hindfoot contact is prolonged during the simulation compared to the measurements.

DISCUSSION

The newly developed contact model showed a good performance in predicting the peak PP over time. With respect to finite element contact simulation, this contact model allows a continuous simulation of PP at a limited time. Due to its characteristics this contact model has potential to be used in the design of insoles and customized footwear.

REFERENCES

Figure 1: The plots show the measured (gray) and simulated (red) peak pressure curves for the 4 regions: whole foot, forefoot, midfoot and hindfoot, subdivided using anatomical marking [2]. The curves are averaged over the 10 subjects, with its nominal 95% bootstrap prediction bands [3]. The overlap between the bands is indicated by the colored bar, with blue representing no overlap and red maximal overlap.

SP089.4 - 3D numerical investigation of the effects of altered mechanical loading during skeletal growth

Author(s): Kamel Madi1, Peter D. Lee1, Katherine A. Staines2, Andrew A. Pitsillides3, Andrew J. Bodey1, Brian K. Bay1

1Manchester X-ray Imaging Facility, University of Manchester, Didcot, oox/UNITED KINGDOM, 2The Royal Veterinary College, London/UNITED KINGDOM, 3I13-2 Branchline, Diamond Light Source, Didcot/UNITED KINGDOM, 4School Of Mechanical, Industrial & Manufacturing Engineering, Oregon State University, Corvalis/OR/UNITED STATES OF AMERICA

Purpose

Abnormal growth plate closure during endochondral ossification and subsequent deformity resulting from altered mechanical loading has key implications in the progression of joint deformities such as...
varus and valgus. Despite several studies investigating changes in bone growth in response to mechanical loading [1], there is a lack of 4D data (3D with time) quantifying the relationships between the closure of the growth plate and the local micro-mechanical environment that the cells in the epiphyseal growth plate may experience. We aimed to combine X-ray computed tomography and computational modelling to investigate whether there is a correlation between the 3D high resolution images of growth plate cartilage topology, the octahedral shear stress (believed to promote endochondral ossification [2]) and the spatial localisation of the bridges.

Methods

Synchrotron-based micro-CT imaging of joints from a mouse strain (Str/ort) with natural susceptibility to OA and age-matched CBA (control) mice was performed at different stages of the disease on the Diamond-Manchester Branchline I13-2 (effective pixel size: 1.1 μm). Novel image processing methods were developed to map the location/density of the bridges onto the joint surface and to characterise the 3D topology of the growth plate cartilage. In parallel, 3D volumetric meshes of the entire tibia including the growth plate cartilage were generated from the tomographic images and finite element computations were carried out to simulate static compressive tests (sustained loading).

Results

Compared to control mice, the growth plate cartilage of late-OA joints is thicker with higher local curvature (Fig. 1), suggesting different remodelling and local stress state. Our first micro-FE computations in a late-OA joint revealed that the bridges seem to act as stress concentrators and are hence more likely to fracture under loading and/or to redistribute stresses within these particular vicinities of the growth plate cartilage.

![Fig. 1 Distribution of the local mean curvature in the growth plate cartilage of adult mice.](image)

Conclusions

Our data reveal changes in the internal 3D topology of the growth plate cartilage in a model of spontaneous mouse osteoarthritis that could be linked for the first time to the micro-mechanical environment experienced by the growth plate during skeletal growth. Further investigation at earlier disease stages will reflect how these different topologies impact the stress and strain distributions and whether this may correlate with growth rate, greater bridge cluster-
SP090 - QA Measurements for Therapy Dosimetry

SP090.1 - Response Characteristics of a Large-Area Ion Chamber with Various Radiotherapy Beams

Author(s): Makan Farrokhkhil1, Andrew J. Jung2, Yinkun Wang3, Bern Norrlinger4, Robert K. Heaton4, Mohammad K. Islam4
1Radiation Physics, Princess Margaret Cancer Centre, Toronto/ON/CANADA, 2Radiation Physics, Princess Margaret Hospital, Toronto/ON/CANADA

Introduction: Previously described Integral Quality Monitoring (IQM) system, utilizes a large area gradient ion chamber mounted on the collimator to measure the “dose-area-product” of field segments. The gradient in spatial response is created by a slope in separation between electrode plates. The system verifies the dose delivery by comparing the measured and predicted signals in real-time. Since the signal of the ion chamber is comprised of the beam fluence through the open aperture as well as the attenuated beams through collimating structures, it creates a new dosimetric paradigm in Radiation Therapy. This presentation describes several dosimetric performances of the IQM detector including the response variation with various field sizes, beam energies, dose rates, and spatial sensitivity of treatment fields in several Linear Accelerator (Linac) platforms.

Method: Dosimetric measurements were performed in Elekta Synergy (60 leaf-MLC/i2) and Infinity (160 leaf-Agility), as well as Varian iX and TrueBeam (160 leaf- Millennium) Linacs. The beam energies across these platforms were 6, 10, 18 MV, 6 MV Flattening Filter Free (FFF) and 10 MV FFF. All the beams deliver 1 cGy/ MU for a 10 × 10 cm² field at dmax-depth, with the source to detector distance of 100 cm. The chamber was mounted on the accessory tray of Elekta and the upper wedge tray of Varian Linac.

Results: The chamber signals, expressed in IQM Count, for a 10 × 10 cm² field with 6 MV beams were 1946 and 2259 Counts/MU for TrueBeam and Infinity respectively. The difference in counts can be attributed primarily to: (i) differences in the source to chamber distance (ii) differences in MLC and jaw transmission factors and the back-up jaw configuration. The field size factors for 6 MV beams, normalized to a 10 × 10 cm² field, ranged from 0.008 to 4.352 for TrueBeam and 0.023 to 3.941 for Infinity for fields ranging from 1 × 1 cm² and 20 × 20 cm² respectively. The relative energy response varies widely with field size, machine model, and beam filtration. A maximum difference in response for 10 MV, 18 MV, 6 MV FFF and 10 MV FFF beams, relative to 6 MV beams in corresponding Linac were found be 20.6, 23.4, 23.9, and 39.4% for field sizes ranging from 1 × 1 cm² to 20 × 20 cm². When a 3 × 3 cm² field was shifted by 3.0 cm in the direction of increasing gradient, signal difference of up to 12 % and 10 % were observed for TrueBeam’s 10 and 6 MV beams respectively. For a 10 VM FFF beams however, no measurable difference in signal was observed for the same shift, due to the combined effect of chamber gradient and off-axis profile.

Conclusion: Since the IQM Chamber intercepts the entire projected area defined by the primary jaws, the signal is comprised of the open beam and the attenuated beam through the MLC and jaws. A significant difference in some key dosimetric response is therefore expected across various beam energy, filtration and Linac models.

SP090.2 - Very small circular fields output factors: Comparison of MC calculations, EBT3 film and micro-diamond measurements

Author(s): Eyad A. Alhakeem1, Sergei Zavgorodni2
1Physics & Astronomy, University of Victoria, Victoria/CANADA, 2Medical Physics, BC Cancer Agency, Victoria/CANADA

The purpose of this work was to obtain output factors (OFs) of 6MV beam collimated by customized circular cones of 1.3 and 3.5 mm diameter at isocenter. We also compared OFs from these cones with OFs from BrainLab™ of 10, 12.5, 15 and 40 mm cones.

OFs were measured using GafChromic EBT3 films and micro-diamond detector. Detectors were placed isocentrically in a water phantom at 1.5 cm depth. Two sets of EBT3 measurements were extracted from different image resolutions as shown in Table 1. Micro-diamond detector was also used to measure cone OFs with detector axis orthogonal to the incident beam. BEAMnrc/DOXYZnrc codes were used to calculate OFs and dose profiles in water with 1x1x1 mm³ voxels for the 10-40 mm cones and 0.1x0.1x0.1 mm³ voxels for the 1.3 and 3.5 mm cones, respectively.

Results for OFs (relative to 40 mm diameter cone) are shown in Table 1. Differences of 15.4% and 15.9% were found for cone 1.3 and 3.5, respectively. Maximum differences of up to 4.0%, 2.9% and 1.9% were found for cones 10, 12.5 and 15 mm, respectively. Scanning resolution of the films was critical for the two smallest fields and the differences between two EBT3 OF’s measurement set were 6.7% and 14.3% for cone 3.5 and 1.3, respectively.

In conclusion, differences in output factor were within 4% for cones with 10 mm diameter and greater. However, larger differences were observed for the 3.5 and 1.3 mm field sizes. Scanning resolution has significant effect on the output factor of the smallest cones in this work.

Table 1. Output factors measured and calculated for a range of circular cones. Statistical uncertainty of MC calculations was within ±2.5%.

SP090.3 - Investigation of pass rate variability in ArcCheck measurements

Author(s): Harald Keller1, Albert Chen2, Daniel Létourneau2
1Radiation Oncology, University of Toronto, Toronto/ON/CANADA, 2Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/ON/CANADA

Spine SBRT (stereotactic body radiation therapy) is an emergent radiation therapy treatment technique for bone metastasis in the spine. Such treatments are nowadays delivered using volumetric modulated arc therapy (VMAT). The ArcCheck detector (Sun Nuclear Corporation, Melbourne, FL) is part of the patient-specific QC process to routinely evaluate the ability to accurately deliver VMAT plans. It was found that the results of such ArcCheck measurements
for spine SBRT plans can vary widely from patient to patient, more so than for other treatment sites. The purpose of this work was to investigate potential sources of this variability in order to streamline the QC process for spine SBRT patients.

A set of 144 spine SBRT treatment plans published between July 2012 and May 2014 was available. All plans used a single 360 degree arc with isocenter in the spine. The vast majority of treatment plans were delivered on a single linac (Elekta Beam Modulator (TM)).

Absolute dose pass rates (ADPR) are the percentage of values (detectors) in a measured dose map (cylindrical surface within the ArcCheck phantom) that have passed a set of criteria, usually a 3% dose-difference and 2 mm distance-to-agreement criterion with respect to the calculated dose map obtained from the planning system (Pinnacle, Philips). The number of detectors participating in the comparison is set by a dose threshold (TH).

For this work, the pass rates and their variability were studied for several parameters associated with the measurement and analysis of the dose map: the TH threshold, sensitivity of the results to ArcCheck phantom (dose map) shifts, global and local gradients in the measured dose maps and the degree of beam modulation as assessed by the number of monitor units per delivered dose (MU/cGy) of the arc. For efficient analysis, an emulation of the pass rate algorithm was implemented in Matlab and validated against the commercial software (SNC patient, Sun Nuclear).

The ArcCheck results for the spine SBRT plan set showed a mean ADPR of 86% with a wide range between 60% and 98%. ADPR was largely constant for most patients as a function of TH, except for TH below 10% where most pass rates dropped significantly and increased variability within the set. As expected, ADPR decreased with applied dose map shift for most instances, but ADPR was not correlated to the degree of ADPR sensitivity to these dose map shifts. The within-set ADPR variability was almost independent of “flatness” of the dose map (quantified as the sum of the gradient taken over the dose map). Only for very flat dose maps with small gradients the ADPR was consistently above the set mean (around 90%). Degree of beam modulation had some correlation with ADPR (correlation coefficient 0.608) where higher/lower beam modulation resulted in lower/higher pass rates, respectively.

In summary, there is no known single parameter that is driving the variability of the ADPR. Multivariate analysis should be performed and parameters that influence the computation of the dose map need to be incorporated as well.

SP090.4 - Characterization and image quality evaluation for a clinical 2.5 MV in-line portal imaging beam

Characterization and image quality evaluation for a clinical 2.5 MV in-line portal imaging beam

Recently, a 2.5 MV inline portal imaging beam has been made available on Varian TrueBeam™ Linacs. The aim of this work is to present our initial investigations of the 2.5 MV beam characterization and imaging quality assessment.

The 2.5 MV beam output was calibrated following the AAPM TG-51 procedure. The beam output has been stable over four months to within 1%. The PDD was measured with a CC13 chamber, a Markus chamber, and Gafchromic EBT3. The resulting depth of maximum dose, dmax, and PDD at 10 cm depth (%dd(10)) was measured to be 5.7 mm (51.7%), 6.1 mm (51.9%), and 5.1 mm (51.9%) for a 10x10 cm² field size at 100 cm SSD for the CC13, Markus and EBT3 film, respectively (Figure 1). The beam quality is slightly lower than that of a 60Co beam; however we estimated a kQ value of 1.00 for output calibration purposes. Additionally, the measured HVL was 9.8 mm Cu (14.8 mm Cu for 60Co), corresponding to an effective energy of approximately 550 keV. The relative entrance dose as measured with EBT3 films was 63%, compared to 23% for a 6 MV beam.

The image quality was assessed with the Standard Imaging Phantom QC-3. The estimated MTF for the MV-imaging system shows that 2.5 MV has better spatial resolution than the 6 MV beam (Figure 2). The 2.5 MV exhibited nearly three times higher surface dose than the 6 MV, however, for a separation of 20 cm, the 2.5 MV mid-separation dose is 78% of the 6 MV dose and the exit is only 58% of the 6 MV dose. Future work will focus on the clinical implementation and development of quality control protocols for this novel imaging beam modality.

Figure 1. Percentage-depth dose plots of the 2.5 MV imaging beam measured with EBT3 Gafchromic film, a CC13 ion chamber, and a Markus ion chamber for a 10x10 cm² field at 100 SSD. The entrance dose was measured using EBT3 film placed perpendicularly to the beam on a solid water phantom.

Figure 2. Normalized Modulation Transfer Functions (MTF) of both 2.5 MV and 6 MV portal imaging beams, calculated from the Standard Imaging QC3 phantom. The Low Dose mode delivers 1 MU for the 2.5 MV beam and 1.5 MU for the 6 MV beam and the High Resolution mode delivers 1.5 MU and 3 MU for 2.5 MV and 6 MV, respectively. The plots are normalized to the 2.5 MV Low Dose MTF for the 2.5 MV Low Dose and 6 MV Low Dose curves, and to the 2.5 MV High Resolution MTF for the 2.5 MV and 6 MV High Resolution curves.

SP090.5 - Usefulness of the commercialized EPID based dMLC QA tool for Elekta Agility MLC

Author(s): Samiu Cho1, Woonhoon Choi1, Ho Lee1, Kwangwoo Park1, Jungil Lee1, Jeongmin Yoon1, Eungman Lee1, Suk Lee1, Sang Hoon Lee2, Juree Kim2, Jinho Choi2, Sangwook Lim2, Ki Chang Keum3

The dynamic intensity modulated radiation therapy(dIMRT) and volumetric modulated arc therapy (VMAT) requires accurate leaf position, leaf speed, gantry position and gantry speed while modulating the dose rate. The Elekta Agility linear accelerator(Elekta AB, Stockholm, Sweden) could be to meet these characteristic with
als (air, bone and homogeneously with RW3) and different square field sizes (FS) were irradiated to evaluate the isocenter dose in the homogeneous phantom. The global accuracy was assessed by comparing OFs and PDDs evaluated with TPS with that reconstructed by DC.

Then, DC was run pre-treatment and in-vivo for 15 patients: 1) 7 IMRT prostate cases, 2) 3 abdominal VMAT cases, 3) 5 head VMAT cases. Gamma analysis (3%, 3mm) was used to compare measured with calculated dose distribution.

Isocenter dose was equal within 1.75% for pre-treatment and in –treatment measures and for all FS. Due to the use of a pencil beam algorithm, high OF and PDD differences (up to 64.2% and 110%, respectively) were found in the air filled phantom at small FS.

In patients, gamma passing rates evaluated on the whole treatment volume were above 98% and 94% for pre-treatment and in vivo prostate cases respectively; above 92% for both pre-treatment and in vivo abdominal VMAT patients, and above 89% and 73% for head VMAT patients.

In conclusion, DC is capable of successfully reconstruct the dose distribution in the patient from the EPID measured exit fluences, even if a more accurate algorithm is needed when low density regions are involved.

Figure1 Validated EPID images for dMLC QA

The acquisition of images and analysis of results took about 25 min. We performed dMLC QA using same dynamic delivery MLC file for 3 month in the 4 Agility linac MLC and averaged result parameters. These parameter values were established as our reference and tolerance level. We could figure out Agility MLC changing trend using ARTISCAN report tools after the parameters were validated. The EPID based dMLC QA program not only improve the QA procedures by reduce the time consuming process, but also guaranties the dosimetric accuracy of dIMRT and VMAT by verification of MLC/gantry position and speed.

Radio-immunotherapy is one such approach where cancer cells are targeted by vectors labelled with a radioisotope. In a specific case of targeted alpha-therapy (TAT), a tumour-specific antibody/protein is radiolabelled with an alpha-emitting radionuclide, termed a radioimmun conjugate (RIC). This radioimmunoconjugate attaches preferentially to tumour-specific antigens, and releases high-linear energy transfer (LET) α-particles of a few MeV kinetic energy. Alpha radiation has the shortest range and highest energy transfer (and correspondingly high radiobiological effectiveness), resulting in localized but significant ionization damage (e.g. to DNA). Alpha-emitting radioisotopes can be used to kill isolated cells, small cell clusters and to regress tumours [2]. The high-LET α-radiation produces increased rates of DNA double-strand breaks. The LET is ~100keV/μm, giving a higher probability of causing DSBs; ratio SSB/DSB≈20 compared with 60 for low-LET radiation.

Over the past 20 years the development of RICs has enabled TAT to progress from in vitro studies, through to pre-clinical in vivo experiments and clinical trials. The dose to normal tissues provides a limitation to the injected dose and to that received by the tumour. However, TAT can achieve cancer regression within the maximum tolerated dose (MTD) for normal tissues provides a limitation to the injected dose and to that received by the tumour.

过度 linear energy transfer (LET) α-particles of a few MeV kinetic energy. The LET is ~100keV/μm, giving a higher probability of causing DSBs; ratio SSB/DSB≈20 compared with 60 for low-LET radiation.

This lecture gives an overview of clinical results in an endeavor to recommend whether and how TAT and High-Z NPs can be integrated into the therapeutic armamentarium for cancer.

However, for solid tumours the promise of TAT is greatly extended by the development of tumour antivascul ar alpha-therapy (TAVAT); i.e. killing of tumour capillary endothelial cells that results in disrupting of tumour capillary networks and shrinking tumours [5].

High-Z Nanoparticle Radiosensitization

High-Z nanoparticles (NPs) have been a topic of interest in medical research since 1950s. It has, however, only been in the last 20 years that the practical use of NPs for imaging and radiotherapy has been demonstrated [6]. It has been shown that the presence of gold (or other high-Z material) nanoparticles improves the cell-killing effect of radiation in vitro and with in vivo mouse models. High-Z nanoparticles are being used in human trials for sensitization of tumour in radiation therapy, yet the mechanisms of enhancement are still being investigated [7, 8].

In a specific case of gold, NPs generally have an individual diameter between 1nm-1μm and are suspended in an aqueous solution. The high atomic number of gold relative to tissue means that when gold is introduced into a tumour, it acts as a contrast agent for imaging and it amplifies the biological damage in the case of external beam therapy. Cell death after radiotherapy occurs due to DNA damage induced by Reactive Oxygen Species (ROS). The ROS are generated from interactions of the incident radiation with atoms, emissions and scattering from those atoms, and subsequent interaction with oxygen based molecules. This process relies on emission of photo-electrons and Auger electrons, Compton Scattering, and Pair production.

Increasing localized dose deposition can improve therapeutic outcome, but needs to be done so that healthy tissues are not compromised by spurious dose deposition that nanoparticles may cause. It is very difficult to quantitatively analyse a statistically relevant number of individual cells for both nanoparticle content and biological markers. X-ray-Fluorescence (XRF) microscopy can be used to correlate nanoparticle content of individual cells with biological consequence to identify specific mechanisms of radiosensitization. This information is critical for understanding implications of such technologies as they move into human trials. XRF microscopy has only recently been able to rapidly image large area samples, and is uniquely available at the Australian Synchrotron [9]. This is a notable advance in the technique and is unique in the world. It can be used to quantify the mass of gold in each cell and hence deduce the number of nanoparticles. Subsequently, number of DNA breaks and Au content can be correlated to investigate the role of variables.

SP091.2 - Enhanced uptake of gold nanoparticles coated with polyethylene glycol
Author(s): Charmaine Cruje, Devika B. Chithrani
Department Of Physics, Ryerson University, Toronto/ON/CANADA

Polyethylene glycol (PEG) has promoted the prospective cancer treatment applications of gold nanoparticles (GNPs). In vivo stealth of GNPs coated with PEG (PEG-GNPs) takes advantage of the enhanced permeability and retention effect in tumor environments, making them suitable for targeted treatment. Because PEG minimizes gold surface exposure, PEG-GNP interaction with ligands that mediate cancer cell uptake is lower than uncoated GNPs. Hence, the cellular uptake of PEG-GNPs is significantly lower than uncoated GNPs in vitro. As intracellular localization of GNPs maximizes its therapeutic enhancement, there is a need to improve the uptake of PEG-GNPs. To enhance uptake, a peptide sequence containing an integrin receptor binding site, or RGD, was conjugated with PEG-GNPs of varying core sizes. Spherical GNPs of diameters 14, 50 and 70 nm and a PEG chain length of 2 and 5 kDa were used to determine a preferred core size and chain length for uptake in vitro and in HeLa and MDA-MB-231 cells. Results show that enhanced cancer cell uptake may be achieved with the peptide sequence used for all sizes of PEG-GNPs in HeLa cells. For MDA-MB-231 cells, higher cancer cell entry was observed less significantly and only for a size of 14 nm. Hence, improved cancer cell entry of PEG-GNPs into HeLa cells may be achieved with the use of an RGD peptide, while a different peptide sequence would have to be used for MDA-MB-231 cells.

SP091.3 - Nuclear targeting of gold nanoparticles for improved therapeutics
Author(s): Celina J. Yang, Devika B. Chithrani
Biomedical Physics, Ryerson University, Toronto/CANADA

The combining of nanotechnology and medicine is gaining more and more interest in the field of biomedical sciences. Gold nanoparticles (GNPs) have been extensively used in cancer research due to their ability to act as an anti-cancer drug carrier for chemotherapy and as a dose enhancer in radiotherapy. Most GNP research in the past involved a system where GNPs were in the cytoplasm of the cell as unmodified GNPs enter the cell through a receptor mediated endocytosis. However, it is predicted that therapy response can be further enhanced if GNPs can be effectively targeted into the nucleus. Nuclear targeting requires a modification to the GNPs to escape the regular endo-lyso pathway and target to the nucleus. An effective strategy for designing a GNP-peptide complex for targeting the nucleus will be presented. Two different sequences of peptides where conjugated onto GNPs. The role of one peptide enhanced the uptake into the cell, while the other induced nuclear delivery. With nuclear targeting, there is a possibility in producing additional low-energy secondary electrons in response to irradiation within the nucleus. This can cause more damage to the DNA. This research will establish a more successful NP-based platform for combining treatment modalities that can lead to a more effective approach in the treatment of cancer.

SP092 - Neural Signal Processing: Part 1

SP092.1 - Delta-Modulated High Frequency Oscillations Linked to Pathological Brain in Female Mecp2-Deficient Mice
Author(s): Sinisa Colic1, Min Lang2, Rob Wither3, Liang Zhang4, James H. Eubanks5, Berj L. Bardakjian6
1Electrical And Computer Engineering, University of Toronto, Toronto/CANADA, 2Department Of Physiology, University of Toronto, Toronto/CANADA, 3Department Of Neurology, University of Toronto, Toronto/ON/CANADA, 4Department Of Surgery, University of Toronto, Toronto/CANADA, 5Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA

Mutations in the X-linked gene encoding methyl CpG-binding protein 2 (MeCP2) have been linked to a neurodevelopmental disorder known as Rett syndrome. Rett syndrome is predominantly found in females, occurring 1 in 10,000 live births. Among other impairments the clinical manifestation of Rett syndrome typically involves epileptic seizures, providing a unique genetic model of epilepsy. Me Cp2-deficient mouse models recapitulating many of the deficits of Rett syndrome have been developed to examine the seizure-like activity from intracellular electroencephalogram (iEEG) recordings. The majority of the studies to date have focused their analyses on the low frequency oscillations (LFOs) associated with the epileptiform discharge rhythm occurring in the 6 – 10 Hz frequency range. However, some more recent studies on Mecp2-deficient mice have revealed the existence of high frequency oscillations (HFOs) in the frequency range 80 – 600 Hz and shown that these HFOs interact with the phase of the LFOs. HFOs are an important clinical biomarker for seizure-onset zone, often used by clinicians to determine resection areas in patients with intractable epilepsy. Furthermore, recent clinical studies are suggesting that by examining the LFO-HFO interactions it may be possible to achieve a more accurate identification of the epileptogenic zone which would potentially lead to more successful resection outcomes. In this study the coupling of HFOs to the phase of the LFOs was examined in female Mecp2-deficient mice before and after mecp2 gene reactivation therapy. Our analyses show that the modulations could be subdivided into two distinct categories, coupling between the phase of the delta LFO (3 – 6 Hz) with the amplitude of the fast ripple HFO (400 – 600 Hz) and coupling between the phase of the theta LFO (6 – 10 Hz) with the amplitude of the fast ripple HFO (400 – 600 Hz). Examining the differences in modulation before and after mecp2 gene reactivation revealed that the delta with fast ripple modulation was abolished, whereas the theta with fast ripple modulation diminished. This matches the findings of a recent clinical study showing that the modulation of the delta with the fast ripple was an indicator for epileptogenic onset zone, and when that region was resected it would lead to successful surgical outcome. As the mecp2 gene is reactivated the animals show significant improvements suggesting that an interplay exists between the delta LFOs and the fast ripple HFOs leading to a pathological brain. Understanding this interaction could potentially be used as a biomarker for accurately identifying pathological seizure activity and potentially lead to better treatment outcomes.

SPO92.2 - Contrast between Spectral and Connectivity Features for Electroencephalography based Authentication

Author(s): Chunjung Han1, Sangkyong K. Kim1, Heenam N. Yoon1, Wonkyu K. Lee1, Cheoolsoo S. Park1, Kokeun K. Kim1, Kwang Suk Park1
1Interdisciplinary Program Of Bioengineering, Seoul National University, Seoul/KOREA, 2Department Of Computer Engineering, Kwangwoon University, Seoul/KOREA, 3Center for Cognition and Sociality, Institute for Basic Science, Seoul/KOREA, 4Department Of Biomedical Engineering, The College Of Medicine, Seoul National University, Seoul/KOREA

Biometrics using electroencephalography (EEG) have received attention as a strong security method and has been investigated by many researchers. Studies applied spectral and connectivity features to identify individuals. However, comparison of spectral and connectivity features are not yet conducted in the aspect of stability. In this paper, we present contrast between spectral and connectivity features for EEG based authentication with signals measured in different days. Spectral features are represented as power spectrum density (PSD) over 2-40Hz with 1Hz resolution provided from each channel. Connectivity features are presented as coherence (COH) of two channels combined, frequency range of 2-40Hz with 1Hz resolution. Total of 20 subjects participated and measured 32 channels of EEG for 10 seconds in eyes-closed resting state in three different days. We evaluated false authentication rate (FAR), false rejection rate (FRR) and half total error rate (HTER) as performance of authentication system designed: by using data measured in first day as train data (600 trials) and others as test data (1,173 trials). The similarity of data is measured using correlation modified Euclidean distance. During the decision making process, two values of threshold were set. The results were achieved with minimum of 10.45% HTER when using PSD, and 17.45% of HTER when using COH. It is well known that PSD features are relatively stable over time thus we post-analyzed coherence characteristics of EEG measured over three different days to evaluate stability. To assure stability, those that failed to reject ANOVA and highly correlated (over 0.8) were filtered in each subject in alpha band (8-13Hz) and composed coherence map for each participant. We concluded that considering both PSD and COH, feature filtering is necessary in order to guarantee efficient EEG based authentication.

SPO92.3 - EMG artifact removal using ICA-based dipole distribution from scalp EEG of epileptic patients

Author(s): Chunsheng Li1, Daniel Jacob1, Trevor Hilton1, Jose Martin Del Campo2, Peter L. Carlen1, Berj L. Bardakjian1
1Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/Canada, 2Toronto Western Hospital, Toronto/Canada

Biomarkers used to guide the resection of the epileptogenic zone depend on proper placement of intracranial electrode sets, which in turn depend on analysis of scalp EEG. Under normal conditions, such signals are contaminated by muscle artifact. Neck, eye, face and mouth muscles are major sources of this artifact. Due to volume conduction, the artifact can be detected across the entire head. In this study, we introduce an artifact removal method based on independent source analysis to identify the generator of the muscle artifact. The goal is to objectively identify the components which would otherwise require time-consuming manual inspection.

Methods:

The proposed method examines the dipole source distribution of the independent components (ICs) produced by independent component analysis (ICA) with respect to the underlying muscle anatomy, as well as their spectral characteristics. Firstly, dipole fitting method (DIPFIT) is used to reconstruct each IC’s dipole in a four layer head model. The head model is divided by seven regions based on the anatomical basis shown in Fig. 1.

Fig.1 Sphere space partition, central region (R0), forehead (R1), temporal (R2), occipital (R3), mouth (R4), neck (R5) and outside regions (R6). (Adapted from Shackman et al. 2009).

Each dipole is assigned to one of the seven regions. Dipoles assigned to R0 are assumed to be EMG free since there are no muscle sources in that region. All other regions contain functionally independent EMG sources which can be identified by computing various spectral signatures. For example, the linear decrease of EEG power spectrum with linear increasing log frequency can be used in identification of an EMG component. Other signatures include peaks in frontalis activity around 25Hz, whereas temporals generates a low peak around 20Hz and broad plateau centered around 40–80 Hz (Goncharova et al. 2003). Scalp EEG for 4 patients with epilepsy from the Toronto Western Hospital was analyzed.

Results:

Combining the dipole distribution and spectral characteristics, artificial ICs can be removed. Sources modeled from synchronous iEEG data are used to validate sources modeled from the artifact-removed EEG.

This work is supported by NSERC, CIHR, and China Scholarship Council.

SPO92.4 - Power based features of epileptic iEEG rhythms to demarcate brain regions for resection

Author(s): Joshua A. Dian1, Yotin Chinvaran1, Peter L. Carlen1, Berj L. Bardakjian1
1University of Toronto, Toronto/Canada, 2Phramongkutklao Hospital, Bangkok/Thailand

Epilepsy impacts up to 1% of the populations and despite optimal care with anticonvulsant medications 39% of patients continue to suffer uncontrolled seizures. Resection surgery provides a subset of these patients an alternative treatment which promises seizure freedom; however, identification of regions suitable for resection remains a challenging problem and results in many patients not achieving meaningful improvement despite surgery.
Intracranial EEG (iEEG) data was obtained from grid electrodes (8x8 or 8x6) implanted in epilepsy patients in preparation for resection surgery. Recorded time series were filtered to remove line noise and differentially referenced resulting in 4x8 or 4x6 channel grids. Previous studies have identified low frequency oscillations (LFO) (<30 Hz) and their relationship with high frequency oscillations (HFO) (>80 Hz) as key markers in classifying ictal events and delineating the epileptogenic zone. In particular, our group has previously shown that amplitude modulation of the HFO activity by the delta rhythm can be used to delineate electrodes of interest for resection.

Here we investigate the use of computationally efficient power based features of the iEEG in order to identify target regions suitable for resection. Empirical mode decomposition (EMD) was used to extract rhythmic components of the iEEG which corresponded to both LFOs and HFOs. Power ratios computed on temporal windows of the extracted LFOs and HFOs formed the feature space. A support vector machine (SVM) classifier was trained/validated using the features extracted from Engel Class I patients and was subsequently used to identify grid electrodes suited for resection. Consistent with previous reports, classification accuracy was state dependent as the characteristic features varied at different phases of the ictal event. The classifier was further able to selectively mark electrodes that were consistent with good surgical outcomes (Engel Class I).

SPO92.5 - The alpha rhythm in a rodent model of epilepsy is enhanced when adenosine receptors are blocked

Author(s): Vanessa Breton, Peter Carlen, Berj L. Bardakjian
University of Toronto, Toronto/CANADA

There are observable spectral markers of seizures in the electroencephalograms and intracranial recordings of epileptic patients. A closer inspection of the pathological rhythms underlying these seizures may aid in the identification of certain neuronal and glial cell populations or synaptic networks involved in the transition through the seizure events. In epilepsy, it has been suggested that the ketogenic diet has a therapeutic effect on seizures by metabolically down-regulating the enzyme adenosine kinase thereby increasing ambient adenosine and activating the adenosine A1 receptor in the cortex. During seizures, it has been proposed that adenosine levels rise, which cause binding of this ligand pre- and post-synaptically to these A1 receptors, inhibiting the excitatory synaptic network and terminating seizures. Mice that have been kindled with pentylentetrazol treatment experience generalized seizures and show an increase in the cell surface expression of the A1 receptor in many brain regions, including the somatosensory cortex. This finding validates the use of a mouse model of epilepsy in the study of the adenosinergic actions on seizures. What has yet to be identified is the direct effect of the adenosine-A1 receptor complex on the rhythms underlying these epileptic events. The purpose of this investigation is to first assess whether or not a common rodent cortical seizure model shows similar spectral features as clinical cases, and then whether or not there is a pathological frequency band that is restrained due to the presence of extracellular adenosine. Local field potentials were recorded from 500um thick coronal slices from layers 2 and 3 of the mouse somatosensory cortex. Omitting the magnesium in the extracellular artificial cerebral spinal fluid induced two forms of spontaneous field events: long duration seizure like activity and short duration bursts. The pathological oscillations underlying these bursting events were characterized by time-frequency spectral analysis using the continuous wavelet transform. The A1 receptor antagonist DPCPX was applied extracellarily at various concentrations. Dose dependent changes in the power of certain frequency bands were quantified. This model was shown to contain pathological rhythms in the delta (1-3Hz) and theta (4-8Hz) bands. It has been observed that although this antagonist does not significantly alter the duration of the long duration seizure like events, it does increase the total number of shorter duration bursts between these events and selectively enhances the overall power of the alpha rhythm (9-14Hz) in a dose dependent manner. During the initial phase of the long duration seizure like events the power of the alpha rhythm was enhanced under DPCPX + low magnesium compared to similar intervals taken from seizure like events in the low magnesium model. The change in rhythms underlying subsequent phases of the long duration seizures and short duration bursts are currently being characterized.

SP093.1 - The maintenance needs of oxygen concentrators in low-resource settings and implications for technician training: Experience from The Gambia

Author(s): Beverly D. Bradley1, Samantha Chow2, Ebrima Nyassi3, David Peet4, Yu-Ling Cheng5, Stephen R. Howie6
1Centre For Global Engineering, University of Toronto, Toronto/ CANADA, 2University of Toronto/Toronto/CANADA, 3Biomedical Engineering, Medical Research Council Unit The Gambia, Fajara/GAMBIA, 4Ashdown Consultants, Essex/UNITED KINGDOM, 5Child Survival, Medical Research Council Unit The Gambia, Fajara/GAMBIA

Oxygen is an essential medicine for treating pneumonia, the leading cause of death in children under five worldwide. Yet, providing a sufficient and reliable supply of oxygen is a major challenge for many health facilities in the developing world, particularly in paediatric care units. The cost-effectiveness of oxygen concentrators versus compressed gas cylinders as a source of oxygen in low-resource health facilities has been demonstrated. However, some maintenance and repairs are required to optimize their longevity. To date, evidence of their long-term functionality in the field has been scarce.

The Biomedical Engineering Department at the Medical Research Council Unit in The Gambia manages and maintains 27 oxygen concentrators at several sites across the country, and has kept electronic records of all repairs and preventive maintenance (PM) on these devices since 2006. Through a retrospective analysis of about 800 repair and PM records between 2006 and 2013, we found that the majority of concentrator repairs were low-cost and required a low technical experience level to complete. For example, the most common repairs were filter, battery or valve replacements, and faulty tubing - all were repairable for less than US$10 each. Median cost of replacement parts per concentrator over the entire analysis period was US$9.44 [interquartile range: US$0, US$63.40]. Seven expensive and complex repairs were rare, and typically occurred after 2.5 years of operation. The concentrators had received an average of over three PM checks per year. Of the 27 concentrators introduced since 2006, 85% are still in service with a median age of over 6 years. We estimate that the useful lifespan of oxygen concentrators in low-resource settings could reasonably exceed 7 years provided a system is in place for repairs and preventive maintenance.

Additionally, we used these repair data for a skill-mapping analysis whereby we identified 31 basic biomedical engineering technician skills that would be sufficient for the repair of over 90% of observed oxygen concentrator failures. Most of the skills identified were drawn from the library of Biomedical Technician Assistant (BTA) skills developed by Duke University’s Developing World Healthcare Technologies Lab and Engineering World Health (http://library.ewh.org). Each of these skills can be taught to a BTA in 2 hours. We used this skill-mapping analysis to propose an evidence-based training curriculum specifically tailored to the maintenance of oxygen concentrators in low-resource settings.

This work has provided insight into the broader support ecosystem required to manage and maintain oxygen concentrators and other low-complexity medical devices in low-resource settings. Specifically, some of the key elements for the successful use of oxygen concentrators in our Gambian setting have been: uniform and context-appropriate device selection; trained technicians and an established health technology management program; a system for routine preventive maintenance; and resources for and access to spare parts. With this support ecosystem in place, oxygen concentrators can be an appropriate and low-cost technology for supplying medical oxygen in low-resource settings.

SP093.2 - Global Medical Devices Pricing Survey

Author(s): Adriana Velazquez Berumen, Maria E. Moreno Carbajal, Olumurejwa Fatunde, Yael A. Rodríguez-Guadarrama
His/emp/pau/medical Devices, World Health Organization Headquarters, Geneva/SWITZERLAND

To guarantee equitable access to medical devices, reliable information must be available for policy-makers and procurers. Due to lack of information on medical devices pricing, Low and Middle-Income Countries (LMIC) face several disparities during the acquisition process; a public procurer in Latin America paid 300% more for the same device as a public sector organization in Europe. A few countries, such as Brazil, Japan, and Iran have made several efforts to provide reference information to procurers within their countries. However, the majority of countries have no such information available. Since health technology is an essential building block to achieving Universal Health Coverage, information transparency and pricing regulation should treated as priorities by high-level health authorities.

Since 2011, the WHO Medical Devices Unit has begun to address the issue of pricing inequity by building an evidence base. Two studies have been completed by the Medical Devices Unit. The first study detailed price components throughout the supply chain as well as a breakdown of the operational costs generated by 7 selected medical devices (excluding medicines, drugs and vaccines). This study conducted a pilot survey that includes defined parameters to measure price components and operating costs of medical devices over a worldwide representative countries sample and industry sector. The second study provided a conceptual framework for financial access to medical devices. This work supported the pilot of Global Medical Devices Pricing Survey (GMDS), which was launched in 2013. For the GMDS, quantitative information on price components of 21 medical devices were collected from several stakeholders within the health sector, qualitative information on procurement, industry and trade were collected as well. Technologies, brands and models were selected thorough research and evaluation of the products used most commonly throughout the world.

Results from surveys derived from these studies shared a common dilemma: a lack of responses with comparable and useful information. In the first case, only 6 out of 24 countries had completed the survey. For the GMDS, only 15 organizations worldwide submitted responses. Most survey responders chose to report general information on industry, procurement, and trade, rather than medical devices price components. As a result, it is necessary to do an extensive review of the selected medical devices as well as the surveyed participants.

In order to improve global data collection for the forthcoming GMDS, WHO is taking into account the outcomes of the pilot of GMDS, the Global Atlas of Medical Devices (GAMD) 2013 and efforts made by other countries. This includes redefining qualitative information and reselection of medical devices to be included on the
Availability of reliable information on medical devices pricing is the first step in the long path to achieve transparency and pricing regulation policy, possible solutions for disparities within the medical devices market for LIMC.

**SP093.3 - Methodology to evaluate physical environment parameters in healthcare services**

**Author(s):** Gustavo A. Elias\(^1\), Saide Calil\(^2\)

\(^1\)Department Of Electronics And Biomedical Engineering, CEFET-MG, Belo Horizonte/BRAZIL, \(^2\)Department Of Biomedical Engineering, Unicamp, Campinas/BRAZIL

The physical environment in hospitals should provide adequate conditions in terms of lighting, thermal comfort, air quality, noise level, and workplace. If such conditions are not appropriate, both workers and patients may be negatively affected. The main objective of this work is to develop a human factors and ergonomics based methodology to enable the evaluation of the physical environment in patient care areas. In order to do so, the methodology was developed according to six steps. First, literature research was performed to determine the parameters to be evaluated, which were, then, organized in six groups: work area, noise, lighting, environmental parameters, power outlets, and medical gas outlets. Second, three methods to evaluate the selected parameters were defined: measurement, observation, and written survey. In the third step two forms were created to aid in the parameters measurement and observations. The fourth step involved the development of a written survey in the form of a questionnaire to be applied to healthcare staff. The fifth step consisted of the creation of a method to process the collected data (measurements, observations, and written survey). Finally, in the sixth step, dashboards were developed to report the collected data. The methodology was applied in two intensive care units (ICU) of a public teaching hospital, generating two reports. The analysis of these reports showed that the temperature, relative humidity, and noise in some ICUs were not always in accordance with the established limits. Moreover, the fact that some workers were negatively affected by physical environment parameters such as noise, lighting, and temperature could be verified through survey answers. In addition, there were complaints regarding risk of slip, trip or fall; reflex, glare or shadows; annoying drafts, unpleasant odors, and air quality; as well as the number and positioning of power outlets and medical gas outlets. The methodology met its targets, having generated results that allowed the diagnosis of the effect of some environmental parameters on workers. In addition, the ICU clinical board used the study results in order to develop a campaign aiming at noise reduction.

**SP093.4 - HB-HTA method for the evaluation of exclusive Medical Devices**

**Author(s):** Paolo Lago, Ilaria Vallone, Antonio Scarso, Corrado Gemma, Cosimino Russo

Clinical Engineering Dept., San Matteo Hospital, Pavia/ITALY

**Introduction:**

The Hospital Based Health Technology Assessment (HB-HTA) method is applied to the purchasing process of exclusive and so called “irreplaceable” medical devices, to support the decision of hospital managers.

**Objectives:**

According to Lombardy region rules for transparency and anticorruption, our hospital adopted a standard procedure for the assessment of exclusive medical devices. It involves a panel of experts: clinical engineers, physicians and economists. Clinical Engineering Department collects informations and collaborates with healthcare professionals in order to write short reports about each technology for hospital decision makers.

**Methods:**

The evaluation method, according to HB-HTA approach, is focused on the most important aspects of the clinical use of the technology such as security, reliability and organization impact.

The standard procedure starts with the compilation of a form in which physicians describe the clinical needs related to a specific innovative medical device, then a scientific literature research and a market survey are carried on. From the data collected in the Italian Medical Devices Database (CND Classification) of the Ministry of Health, possible technical and clinical alternatives are evaluated and compared.

**Conclusion:**

The final aim of Medical Device assessment is a structured report for healthcare management. Quality informations make decisions more robust, consistent, transparent and verifiable in order to maximize the health gains for the patients and to minimize costs and resources, through a better purchasing method.

**SP093.5 - Applying Heuristic Evaluation on Medical Devices User Manuals**

**Author(s):** Fernando O. Andrade, Leonardo N. Novaes, Guilherme A. Wood, Saide Calil

Department Of Biomedical Engineering (deb), State University of Campinas (UNICAMP), Campinas/BRAZIL

Driven by the importance of user manuals as a complement to training courses on the operation of medical devices, the objective of this paper is to verify if the heuristic evaluation approach proposed by Zhang and co-authors is applicable to such manuals. After applying the method in the evaluation of a non-medical device user manual and finding some difficulties to interpret the original terms and definitions, we adapted some of the usability heuristics so they would be more directly related to manuals than to devices. The adapted heuristics were applied on the usability evaluation of a linear peristaltic infusion pump's user manual. Although no healthcare professionals were present in the evaluation team, heuristic violations associated to diverse usability heuristics were identified, including some classified as usability catastrophes (the ones which could lead to patient's harm). Even with adaptations, members of the team reported difficulties in fo-cusing on the user manual when the current usability problems seemed to be on the medical device itself. Despite the difficul-ties, the evaluation provided enough data on the user manual problems to formulate some corrective recommendations for the device manufacturer. Additional studies are required to confirm if modifications to some of the original fourteen usability heuristics are really necessary and, if so, what adaptations would be most adequate.
SP094 - Biological Modelling

SP094.1 - Finite Element Analysis of Dynamics of Two Microbubbles Under Ultrasonic Field

Author(s): Xiao-Hui Qiu1, Li Li Zhou1, Yang Yang1, Xiao-Jian Wang2
1Information Engineering Institute, Gannan Normal University, Ganzhou/CHINA, 2Department of Chemosurgery, Ganzhou Tumor Hospital, Ganzhou, China, Ganzhou/CHINA

The finite element numerical model of the two microbubbles in the microvessel is built in our study. The model is solved by finite element analysis software. The pressure of observing point P (away from one of two microbubbles A 3 μm) is used to express the intensity of ultrasonic cavitation. The results show that the pressure on point P is higher than single microbubble case because of the aggravation of the cavitation effect, and with the increasing of the distance of two microbubbles, the effect of adjacent microbubble on point P decreases. These results lay the foundation of the research of the agent concentration effect on clinical diagnosis and treatment.

SP094.2 - The value of individual measurements for tumor control probability predictions in head and neck patients

Author(s): Juliana Toma-Dasu1, Mattias Hedman2, Alexandru Dasu3
1Medical Radiation Physics, Stockholm University and Karolinska Institutet, Stockholm/SWEDEN, 2Department Of Oncology, Karolinska University Hospital, Stockholm/SWEDEN, 3Department Of Radiation Physics, Linköping University Hospital, Linköping/SWEDEN

In the age of personalized medicine, individual measurements of in vitro radiosensitivity and proliferation parameters have great potential for predicting treatment outcome. However, cellular radiosensitivity is quite heterogeneous and therefore concerns exist towards its impact on treatment predictions. It was therefore the purpose of this study to investigate this aspect. Individually-determined radiosensitivities and potential doubling times, as well as tumor volumes from 46 head-and-neck carcinomas treated with radiotherapy, were used to predict tumor control probabilities (TCP) under various biologically-relevant assumptions for heterogeneity in radiosensitivity. TCP predictions were then compared to clinical local control using a ROC curve analysis. The analysis showed that TCP calculated under the assumption of heterogeneous radiosensitivity have the same power of distinguishing between patients with or without local control as from single values for the radiobiological parameters (a sensitivity of 66% and a specificity of 80% for an area under the curve of 0.69). The only difference was in the discrimination criterion (TCP>93% for single parameters and TCP>65% for heterogeneous parameters), illustrating the difference in appearance of the TCP curve under the assumption of heterogeneity. Nevertheless, the results showed that individually determined radiobiological parameters could be quite effective towards predicting treatment outcome for individual patients.

SP094.3 - A Novel Technique for Measuring Electrical Permittivity of Biological Tissues at Low Frequencies (100 KHz or lower)

Author(s): Seyyed Hesabgar1, Karen Lam2, Ravi Menon2, David Holdsworth2, Abbas Samani3
1Medical Biophysics, Western University, London/ON/CANADA, 2Robarts Research Institute, Western University, London/ON/CANADA, 3Electrical & Computer Engineering, Western University, London/ON/CANADA

Accurate measurement of electrical permittivity (EP) of biological tissues is highly important for a broad range of applications including ECT (Electrical Capacitance Tomography), EPT (Electrical Permittivity Tomography), bone health assessment (Meaney et al.), interaction of electromagnetic fields with biological tissues (Peyman et al.) and food quality classifications (Ngadi et al.). As such many researchers in the past three decades have conducted numerous measurements to obtain electrical properties of biological tissues but despite the fact that most of the researchers have traditionally used an open-ended coaxial cable and vector network analyzer (VNA) for their measurements, a robust and accurate method of measuring biological tissues EP especially at low frequencies has not been developed yet. It is noteworthy that, EP imaging at low frequencies has a good potential to provide valuable diagnostic information. Gabriel et al. indicated that the uncertainty and error percentage of using open-ended coaxial probe and VNA which has been applied in the past three decades as a conventional way of measuring biological tissues EP is quite significant at low frequencies. Computer simulation also indicates that the accuracy of EP measurement for ex-vivo biological samples from conventional procedure (using open-ended coaxial probe and VNA) depends highly on the size and thickness of the samples. This implies that an accurate and reliable measurement of biological tissues EP at low frequencies (100 KHz or lower) may not be achievable by using the conventional technique. In this work we introduce a novel and reliable technique which is capable of measuring the EP of biological tissues at low frequencies in an accurate and robust way. In this technique, we use a highly sensitive capacitive sensor we developed in our laboratory. This sensor consists of two plates that sandwich the tissue sample before its electrical excitation followed by highly precise measurement of the capacitance formed by the two plates and the sample. In order to estimate the sample’s EP, an initial guess of the sample’s permittivity along with its known geometry is fed into an inverse Finite-Element (FE) algorithm we developed for this estimation. This algorithm follows a nonlinear optimization framework which changes the sample’s permittivity in its FE model systematically until the capacitance obtained from the FE model matches the experimental capacitance. The last permittivity value is considered as the estimated permittivity of the tissue sample. The mentioned technique has been utilized to extract the EP from ten freshly excised bovine heart and bone samples. Our results indicate that the average EP of 571 F/m and 22418 F/m at 32 KHz for the bone and heart samples which compare well with values reported in the literature. Also the standard deviation of 50.8 F/m and 1609.3 F/m for the mentioned samples are quite low, which suggest that the proposed technique is highly repeatable.

Electrodermal activity (EDA) has become a promising technique for assessing sympathetic nervous system (SNS) arousal. Afferent neurons from the sympathetic axis of the autonomic nervous system innervate eccrine sweat glands, and their activity modulates conductance of an applied current. Sympathetic innervation of sweat glands is revealed in quantifiable fluctuations in skin conductance at the skin’s surface, termed EDA. EDA comprises slow and more rapid transients. Tonic EDA states have been assessed using two main measures: skin conductance level (SCL) and nonspecific skin conductance responses (NS.SCRs). The aforementioned measures require manual scoring and human visual verification in the time domain which is cumbersome and often subjective. Hence, there is a need for quantitative signal processing techniques to assess the SNS arousal. To this end, we applied power spectral density (PSD) analysis to EDA signals in order to determine correlations between frequency-domain EDA index (0.045 to 0.15 Hz) and EDA measures in the time-domain (SCL and NS.SCRs). We employed the same range of frequency used for sympathetic assessment in heart rate variability analysis, which corresponds to low frequency (LF) index. We also tested the ability of those indices to discriminate between levels of sympathetic arousal. Sympathetic arousal was elicited using orthostatic stress (supine, standing and sitting positions). Seven subjects were recruited and 4 minutes of EDA signals were recorded for each position. Two minutes of clean signal (after one minute of starting recording and one minute after asking the subject to change position) were used for further processing. LF-EDA and SCL was weakly correlated ($r = 0.374$, $p = 0.055$); LF-EDA and NS.SCRs more correlated ($r = 0.545$, $p = 0.032$) than SCL. SCL and NS.SCR presented statistically significant differences between sitting and supine, but not between standing and sitting. However, LF-EDA showed statistically significant differences between the three positions. This shows a potential of PSD of EDA for assessing sympathetic arousal under orthostatic stress.

**SP095.2 - Multivariate Analysis Classification Based on Multi-Channel EMG Multisite Microelectrode Recording, Principal Component Analysis, and Hierarchical Clustering**

**Author(s):** Venkateshwarla R. Raju

Biomedical Eng & Neurology & Neurosurgery And, Nizam’s Inst of Medical Sciences (NIMS) University & Hospital, HYDERABAD/INDIA

**Hypothesis/Rationale** The main HYPOTHESIS is that when a Writer’s cramp (WC) subject writes with an abnormal posture, it is difficult to determine if that posture is because of the primary dystonic force or if a compensatory force (applied by the WC subject) has overcome the primary dystonic force and has resulted in that posture. One way to differentiate between those two would be to look at the mirror movements. Mirror movements (MMs) are seen in the right hand (RH) while writing with the left hand (LH). In case the primary dystonic force is resulting in the abnormal posture while writing with right hand, the MMs would be in the same direction i.e., they would be **beconcordant**. If a compensatory force (overcoming the primary dystonia) has resulted in the posture, this would be seen in the MMs which would be in the opposite direction i.e., they would be **discordant**. We hypothesize that there is no EMG recognizable difference in MMs of concordant and discordant subjects. If the data reveal that there are significant differences in MMs of the two groups of subjects (as we expect it to be) our expectation that there is EMG recognizable difference between the groups is justified and the analysis can lead to (clinically) meaningful insight. This study showed significant quantifiable EMG differences in the signals seen while writing with the right and left hands between those writer’s cramp subjects with concordant mirror movements (C group) versus those with discordant mirror movements (D group). These differences were robust and seen in every measure of dispersion, such as in the patterns of significance of f-values for ratios of variances. Cluster analysis and more sophisticated analyses using advanced multivariate techniques leading to effective data summarization and measures of dissimilarity between subjects as reflected in the signals recorded and consequent possible clustering among them, however, did not lead to any meaningful clinical conclusions. These analyses could possibly be applied to longitudinal follow-ups and correlations with a normal control population in future to better comprehend the WC-phenomenon. The work on muscle signals and their application in neurological disorders as well as disabilities of dexterous movement, such as writing and the results in a vast data regarding the functioning on the muscles certainly and gainfully utilized by the biomedical scientists for further modeling of EDA.

**Background:** Prevalence-rate-of-generalized/focal dystonia according to various studies (Muller J and many other scientists) varies from $0.17$ to $0.05$ per 100,000 population and that of focal dystonia varied according to type of dystonia. The prevalence-rate of general dystonia was $5.3$ to $1$ per 100,000 population and that of focal dystonia varied according to type of dystonia. The prevalence-rate of general dystonia was $5.3$ to $1$ per 100,000 population and that of focal dystonia varied according to type of dystonia.

**Objective:** To develop a computational model using the model to develop a new clinical experimental setup, to design and build a multi-channel EMG machine and attempt to differentiate between those with concordant (C) and discordant (D) MMs in WC, in order to establish that there is a quantifiable difference between these two groups.

**SP095.3 - Blanket Fractal Dimension for Estimating Tidal Volume from the Smartphone Acquired Tracheal Sounds:**

**Preliminary Results**

**Author(s):** Natasa Peljin, Bersain Reyes, Ki Chon

Biomedical Engineering, University of Connecticut, Storrs/CT/UNITED STATES OF AMERICA

Tidal volume is one of the parameters used for monitoring respiratory activity. Various methods exist for measuring the tidal volume; however, all of them require the use of specialized equipment. Due to their attractive specifications and portability, smartphones are becoming more popular and suitable for measuring vital signs and health monitoring in nonclinical and everyday settings. In this paper, we propose the use of blanket fractal dimension (BFD) for estimating the tidal volume from a smartphone acquired tracheal sounds. Tracheal sounds, as part of respiratory sounds, are non-stationary and stochastic signals, and as such are suitable for fractal analysis. Blanket method creates a strip around the tracheal signal, thus closely following the changes within the signal. As the signal changes faster, the value of BFD becomes higher. In this study, we recorded tracheal sounds with an Android smartphone, while simultaneously we collected the respiratory inductance plethysmography signal via Respitrace system. Prior to every recording, the Respitrace signal was calibrated with a spirometry system, and the obtained calibration errors were less than 10 % (which is in accordance with the manufacturer's manual). Signals were collected from five (N=5) healthy and non-smoker volunteers. Each volunteer performed the experiment two times; first to obtain linear and
exponential fitting models, and then to fit new data onto the existing models. Thus, the total number of recordings was 10. The estimated volumes were compared to the true values, obtained with a Respitrace signal, which was considered as a reference. These reference volumes were limited to a range from 0.2 to 1 L, as it is the normal breathing range, and consequently, only the corresponding portions of tracheal sounds were used in analysis. Since Shannon entropy (SE) is frequently used as a feature in tracheal sounds’ analyses, we also estimated the tidal volume from the same sounds by using SE. The evaluation of the performed estimation, using BFD and SE methods, was quantified by the normalized root-mean-squared error (NRMSE). The results show that the BFD outperformed the SE (at least twice smaller NRMSE was obtained during both days). The smallest NRMSE error of 15.877 ± 9.246 % (mean ± standard deviation) was obtained with the BFD and exponential model. In addition, it was shown that the fitting curves calculated during the first day of experiments could be successfully used for at least one following day. These results indicate the possibility of obtaining a portable system for tidal volume estimation, which can be used for more than one day without the need to calculate fitting curves during every day’s experiment.

SP095.4 - A Robust and Realistic Framework for Clinical Classification of Myocardial Infarction
Author(s): Yasin Yazıcı\(^1\), Yasin Mamatjan\(^2\)
\(^1\)Zirve University, Gaziantep/TÜRKEM, \(^2\)Mars Centre, Princess Margaret Cancer Center, Toronto/ON/CANADA

Early detection of Myocardial Infarction (MI) or heart attack is important to reduce mortality rate of cardiac diseases and automatically recognize them in order to help the diagnoses and eventually effective treatment of MI patients. Although various advanced algorithms have been published previously, there are a number of issues regarding reproducibility, public availability, clarity that even some of them ‘over fitted’ the classifier and performed biased pre-processing (feature selection) with all the data set to achieve high accuracy. We aim to create a robust and realistic framework for clinical classification of MI. To achieve this, firstly, we set the requirements for realistic clinical evaluation using predictive modelling and validation as well as proposed practical guidelines for reproducibility. Secondly, to detect MI efficiently and accurately, a novel approach based on Stacked Autoencoder (SAE) is used which has deeper representation power and also needs less pre-processing. We also give essential insight on why and how SAE works for different ECG data. Thirdly, we conducted systematic comparisons of the newly proposed SAE method and Continuous Wavelet Transform (CWT) based Linear Discriminant Analysis (LDA) using real ECG data set. Lastly, based on the predefined requirements, we reflected the clinical reality and corrected some other papers mistake while considering the realistic aspect of separating training and testing dataset to avoid ‘over fitting’ and biased feature selection and thus performed cross validation (with 2 level 10 fold cross validation). SAE always outperformed CWT based LDA approach. The accuracy of SAE is 87 % while the biased and ‘over fitted’ model produced an accuracy of over 99 % which is clinically unrealistic. We are improving SAE approach as it is new for ECG application, so there are more room for future improvement. The novel classification approach developed in this paper can reliably and efficiently provide useful information to clinicians and alert when state of the heart patient changes, could help clinicians realistic diagnoses and eventually effective treatment of cardiac patients.

SP095.5 - A Mother Wavelet Selection Algorithm for Respiratory Rate Estimation from Photoplethysmogram
Author(s): Dan Guo, Zhijian Li, Huijun Ding
Department Of Biomedical Engineering, School of Medicine, Shenzhen University, Shenzhen/CHINA

Photoplethysmogram (PPG) is known as a low-cost optical measure for detecting the blood volume changes. Recently, a new attempt at estimating respiratory rate (RR) from PPG signal becomes an active area. It can be implemented by different algorithms among which wavelet based methods are commonly used with good performance achieved. In previous work, several popular mother wavelets, including db10, sym8, bior6.8, rbio6.8 and coif5, are compared and db10 exhibits the best performance on restoring the useful respiratory information from PPG signal. However, the study on the reason why different mother wavelets have different performances on RR estimation as well as how a suitable wavelet can be easily selected is insufficient. In order to explore this issue, a mother wavelet selection algorithm is proposed in this paper shown in the following figure.

![Wavelet Selection Algorithm Diagram](image)

In our approach, the input PPG signal is decomposed by six popular mother wavelets, namely db10, db12, sym8, bior6.8, rbio6.8 and coif5, and the results are compared in terms of the sum of decomposition coefficient magnitudes in every frame. The mother wavelet with maximum value is chosen to extract the wavelet coefficients containing RR information. By using the extracted coefficients, the reconstruction process is applied to form the respiratory waveform. In the experiments, the proposed algorithm is compared with the related six mother wavelets working separately. Two datasets are used, one of which has 21 PPG signal segments recorded by our PPG acquisition system and the other has 16 PPG signal segments randomly selected from the MIMIC database. Two evaluation tools, root mean squared normalized error (RMSNE) and Bland & Altman plot, are adopted. In RMSNE comparison between reference RR and estimated RR, the proposed algorithm obtains the minimum error rates of 2.373% and 1.4% on two datasets respectively. For Bland & Altman plot where smaller range between 95% limits of agreement indicates a better performance on RR estimation, the proposed algorithm obtains the minimum ranges of [-0.013, 0.011] Hz and [-0.003, 0.007] Hz on two datasets respectively. The above evaluation results demonstrate the better performance of the proposed algorithm. In addition, the finding reveals that the mother wavelet with a larger sum of coefficient magnitudes has a better performance on RR estimation from PPG signal which can be used as wavelet selection criteria in this area.

SP095.6 - Mathematical assessment of variability in respiratory airflow patterns
Author(s): Saravanan K. Raman, Christopher Druzgalski
California State University Long Beach, Anaheim/CA/UNITED STATES OF AMERICA

Mathematical approach was used to study and determine unsteady respiratory airflow dynamics for inspiratory and expiratory breathing cycles and to analyze pulmonary data under different levels of ventilatory conditions. The work involved acquiring and processing of respiratory airflow patterns from healthy subjects under varying levels of induced obstruction. A set of mathematical equations based on the Fourier series model were developed to describe the airflow
patterns. Coefficients obtained from the Fourier series model were evaluated to obtain their ranges of values for different levels of ventilations. The goal to assess the airflow mechanics is approached by numerical modeling of the respiratory airflow network. Graphical methods were used to evaluate the goodness of fit and their statistics including the SSE, R-Square, Adj R-Sqr and RMSE. Basic statistical analysis which includes the mean and standard deviation for the airflow signals was obtained. In order to study the variability of airflow limitations, different size mouthpieces were used.

**SP095.7 - Spectral Analysis of Respiratory and Cardiac Signals Using Doppler Radar**  
**Author(s):** Philip Tworzydlo, Adrian D.C. Chan  
*Systems And Computer Engineering, Carleton University, Ottawa/Canada*

Inmate injuries and deaths remain a significant problem for correctional institutions, increasing the need for continuous monitoring of inmates. A Doppler radar device is investigated for use as a contactless method of vital sign monitoring (e.g., breathing and heart rate) in a single cell setting. The recorded radar signal is analysed in both the time domain, and in the frequency domain. The radar signal and its frequency spectrum is compared against the signals and frequency spectrums obtained from an electrocardiogram and a respiratory inductance plethysmography band. The breathing and heart rate estimates obtained from the radar match up with the estimates provided by the respiratory band and electrocardiogram. Results show that the radar device demonstrates good potential for contactless vital sign monitoring.

**SP096 - Optical Imaging: Applications**  
**TRACK 01: IMAGING**

**SP096.1 - Live-cell Raman microspectroscopy to differentiate between normal and malignant ovarian surface epithelial cells**  
**Author(s):** Santa Borel1, Emil A. Prikryl2, Nhung Vuong3, Barbara Vanderhyden3, Brian C. Wilson4, Sangeeta Murugkar2  
1Department Of Medical Biophysics, University of Toronto, Toronto/ON/CANADA, 2Department Of Physics, Carleton University, Ottawa/ON/CANADA, 3Department Of Cellular And Molecular Medicine, University of Ottawa, Ottawa/ON/CANADA, 4Ontario Cancer Institute, Toronto/ON/CANADA

Raman microspectroscopy (RMS) is a non-invasive, label-free optical technique that is based on the inelastic scattering of light by vibrating molecules. It provides a fingerprint of the common molecular bonds in specimens, including cells and tissues. This technique, in conjunction with multivariate statistical analysis methods, has been applied successfully for the label-free classification of living cells based on their molecular composition, which can be correlated to variations in protein, DNA/RNA, and lipid macromolecules. Here, RMS is applied to normal mouse ovarian surface epithelial (MOSE) cells, M0505, and spontaneously-transformed ovarian surface epithelial (STOSE) cells, which are derived from the MOSE cells and are a model for high-grade serous ovarian cancer.

The Raman spectra collected from individual cells undergo initial preprocessing (background subtraction, normalization and noise reduction) to yield true Raman spectra representative of the cells for subsequent statistical analysis. The means of these spectra are shown for both types of cells in Fig. 1. Although the corresponding images (differential interference contrast microscopy) of the MOSE and STOSE cells shown in the inset appear identical, there are clear differences observed in the spectra that are attributed to differences in molecular concentrations. Using Principal Component Analysis (PCA) followed by Linear Discriminant Analysis (LDA), a clear separation of the cells into the two groups (MOSE and STOSE), with the exception of one outlier, is evident in the preliminary data shown in Fig. 2. The objective of this ongoing work is to characterize the spectral differences between the two cell types in order to correlate them with specific molecular or structural changes. The multivariate classification model constructed using such Raman spectra of MOSE and STOSE cells could thereby potentially be utilized for early detection of ovarian cancer.
SP096.2 - Quantitative image analysis of fluorescence endomicroscopy video sequences for mesenchymal stem cell tracking in regenerative lung treatment

Author(s): Jessica R. Perez¹, Norma Ybarra², Frederic Chagnon², Olivier Lesur², Issam El Naqa¹

¹Biomedical Engineering/medical Physics, McGill University, Montreal/CANADA, ²Radiation Oncology, McGill University health center, Montreal/CANADA, ³Sherbrooke University, Sherbrooke/CANADA

Introduction: Fluorescence endomicroscopy is a powerful new minimally invasive tool that allows real-time visualization of fluorescently labeled cells within the lungs in clinical and preclinical models. In the context of regenerative medicine for lung damage, the objective of this project is to gain insight into the behaviour of mesenchymal stem cells (MSCs) in the lung of a rat model of lung injury post-radiotherapy. Interpretation and analysis of large video sequences is important to quantify the efficacy of such treatment under different experimental scenarios. In this work, we are proposing an image segmentation method to quantify the number of cells present in the field of view at each timepoint in the acquired endomicroscopy video sequence.

Materials and Methods: MSCs were labeled in culture with a membrane dye (DiD) prior to administration. MSCs were delivered endotracheally into the lung and followed by fluorescence endomicroscopic imaging. Images were acquired in the red channel (660 nm) through a tracheotomy procedure. We followed the rats for a week period and images were acquired on days 1, 2, 5 and 7. Regarding video sequence analysis, we treated each frame individually as a stand-alone image. We used a granulometry approach to determine the size of objects (cells) present in the image and performed morphological opening to detect them. Opening is a morphological operation that dilates then erodes the image with a selected structuring element, in this case a disk, in order to remove small erroneous objects and only select cells. A threshold was subsequently applied to the resulting image to select fluorescent cells over background and each detected object was counted.

Results: We were able to detect labeled MSCs in the lungs in vivo and followed them for a period of one week. At any given time point during the movie we were able to obtain an estimate of the corresponding number of cells present in the field of view. Figure 1 shows a representative endomicroscopy image with the resulting corresponding cell count of 15 cells. We compared this automated method to manual cell counting on a test set of 30 frames and achieved a good accuracy with a root-mean-squared error (RMSE) of 4 cells per frame.

Conclusion: We determined the feasibility of lung fluorescence endomicroscopy for tracking of MSCs in vivo and developed an automated image analysis method to quantify the number of cells in different experimental conditions.

SP096.3 - Shape-Based Diffuse Optical Tomography for Reconstruction of Photothermal Lesions in Prostate Focal Therapy

Author(s): Robert A. Weersink¹, Jie He², Sahil Chaudhary², Kenwrick Mayo², Brian C. Wilson²

¹Radiation Oncology, University Health Network, Toronto/ON/CANADA, ²University of Toronto, Toronto/CANADA, ³Ontario Cancer Institute, Toronto/ON/CANADA

Near-infrared interstitial photothermal therapy is undergoing clinical trials as an alternative to watchful waiting or radical treatments for patients with low/intermediate-risk focal prostate cancer. MRI-based thermography is currently used to monitor target tumor destruction based on the measured tissue temperature and calculated thermal energy dose. This indirect method of imaging the treatment zone is used to assess if treatment fully covers the target volume while avoiding damage to adjacent normal tissues, particularly the rectal wall. As an alternative, we are developing transrectal diffuse optical tomography (TRDOT) to directly monitor the photothermal therapy by imaging the photocauterization boundary based on changes in tissue optical scattering.

In this presentation, we describe the development of shape-based diffuse optical tomography as applied to the particular problem of monitoring the expanding photothermal lesion. Standard methods of diffuse optical tomography present an ill-posed inverse problem since the number of source-detector combinations is less than the variant parameters (optical properties within the volume). Hence, there are typically no unique solutions for standard DOT reconstructions. Current practice resolves this situation by imposing spatial or spectral constraints on the solutions.

In our clinical problem, the shape of the coagulated/treated tissue rather than the optical properties is of primary interest. We present a shape-based diffuse optical tomography solution in which shape parameters are used to set varying optical properties within the tissue volume. The shape is an ellipse symmetric about its short axis for a general lesion shape plus spherical harmonics to model small variations from the general ellipsoidal shape. The optical properties of the thermal lesion may vary, but with the assumption that these properties are invariant within the lesion shape.

The solution is applied to simulations of photothermal focal therapy, modelling a growing thermal lesion around a linear 10mm diffusing treatment fiber placed 10mm from the prostate wall. The modelled lesion grows in 1mm radius increments to a final radius of 9mm. Tissue scattering of the thermal lesion was set at 4X the scattering of the surrounding tissue, similar to measured tissue results. Axial and longitudinal source-detector configurations relative to the essentially elliptical thermal lesion were modelled.
The shape-based tomography successfully recovered the correct shape of the thermal lesion for lesion radii >3mm, with the error in the radius <0.5mm. Accuracy improved as the radius increased, equivalent to the lesion boundary approaching the prostate surface. Increasing noise added to the simulated data had little impact on the shape recovery: for lesions within 4mm of the prostate surface, radii error < 1mm up to 16% noise, for smaller lesions, ellipse radii error <3 mm when the noise was greater than 10%. Since the actual optical properties of the lesion may be difficult to recover, the robustness of the shape-based tomography to recover a correct solution when the reconstruction assumes different optical properties than the actual properties of the lesion was tested. Over a large range of optical properties, the shape parameters were recovered within ±1mm.

Shape-based DOT is a viable, accurate method of recovering thermal therapy treatment lesions.

SP096.4 - Transrectal diffuse optical tomography to monitor photocoagulation during interstitial photothermal therapy of focal prostate cancer
Author(s): Jie He, Robert A. Weersink, Israel Veilleux, Brian C. Wilson
1Department Of Medical Biophysics, University of Toronto, Toronto/CANADA, 2Radiation Oncology, University Health Network, Toronto/ON/CANADA, 3University Health Network, Toronto/CANADA

Near-infrared interstitial photothermal therapy is undergoing clinical trials as an alternative to watchful waiting or radical treatments for patients with low/intermediate-risk focal prostate cancer. Currently, MRI-based thermography is used to monitor thermal energy delivery and determine indirectly the completeness of the target tumor destruction while avoiding damage to adjacent normal tissues, particularly the rectal wall. As an alternative, transrectal diffuse optical tomography (TRDOT) is being developed to directly monitor the photothermal therapy by imaging the photocoagulation boundary on the changes in tissue optical properties, particularly scattering. Numerical simulations of optical signals were performed using Nifast to assess the sensitivity of changes in the optical signals to a growing coagulated lesion with higher optical scattering contrast to normal tissue, for varying light source-detector separations in both longitudinal and transverse imaging geometries. The simulations were validated experimentally in tissue-simulating phantoms using an existing continuous-wave TRDOT system. A MR compatible TRDOT applicator probe with a source-detector configuration that is capable of acquiring optical measurements and representative of the potential intended clinical use is assembled and used in these experiments. Phantom measurements and numerical simulations provide critical guidance for the optimum design of a further version of the transrectal applicator probe, in achieving maximum sensitivity to the presence of the coagulation boundary and, consequently, the highest accuracy in determining the boundary location relative to the rectal wall.

SP096.5 - The first in vivo, optical images of neuroblasts migrating away from the subventricular zone deep in mouse brain reveal two patterns of migration: implications for future therapeutic use
Author(s): Ben Kemp, Teresa A. Murray
Biomedical Engineering, Louisiana Tech University, Ruston/LA/UNITED STATES OF AMERICA

Neural stem cells exist naturally in the adult brain in humans, mice and other animals. Their existence has sparked hope for treating neurodegenerative diseases, stroke and brain injury. In mammals, adult neural stem cells divide and begin differentiating in one of two bilateral germinal zones. One of these is the lateral subventricular zone (SVZ). Partially differentiated cells exit the SVZ and migrate to other regions of the brain. When neural stem cells in the SVZ of mice begin to differentiate into neural precursor cells, or neuroblasts, they normally travel in clusters to the olfactory bulb. This pathway is called the rostral migratory stream. However, after a cortical injury, some of these migrating cells change course and migrate into the cortex. This has piqued interest in manipulating the mechanisms of neurogenesis to repair neural damage. Yet, what is known about neuroblast migration relies predominantly on brain slice studies. These studies have produced conflicting observations regarding mechanisms that drive proliferation and migration, and the rates of movement. To overcome the limitations and confounds inherent in slice preparations, an in vivo imaging system was created using a permanently implanted, optimized gradient index (GRIN) lens and multiphoton microscopy. The SVZ is in a subcortical region that is beyond the reach of standard multiphoton microscopy. The implanted lens overcomes this depth limitation. A preliminary longitudinal study was conducted using mice that express green fluorescent protein under the dcx promoter to label neuroblasts. This study is the first to produce images of neuroblasts migrating away from the SVZ in live mice. As expected, most neuroblasts traveled in clusters toward the rostral migratory stream. Surprisingly, a few neuroblasts did not travel with a cluster. These individual cells moved at markedly faster rates and frequently changed directions. In future studies, we will determine what factors influence the migratory path of these lone neuroblasts with the goal of redirecting large numbers of neuroblasts for future therapeutic uses.
SP097 - Quantitative Imaging: Part 2

SP097.1 - Ischemia-time dependent CBF threshold for infarction determined in a porcine model of stroke using CT Perfusion and F-18 FFMZ PET imaging

**Author(s):** Eric A. Wright1, Christopher D. D'Esterre2, Laura Morrison2, Neil Cockburn3, Michael Kovacs4, Ting Yim Lee6
1Roberts Research Institute, London/ON/CANADA, 2Department Of Radiology, Foothills Medical Center, Calgary/ CANADA, 3Lawson Health Research Institute, London/ON/CANADA, 4Department Of Medical Imaging, Western University, London/ON/CANADA, 5MediCal Biophysics, The University of Western Ontario, London/CANADA

**Introduction:** CT Perfusion (CTP) derived cerebral blood flow (CBF) has been proposed as the optimal parameter for delineating the infarct core prior to reperfusion (1), however lack of ischemia-time dependent CBF thresholds for infarction has been problematic. Previous CTP-CBF threshold derivation studies have been limited by uncertainties caused by infarct expansion, and DWI lesion reversibility (2). This study proposes a porcine model for determining ischemia-time dependent CBF thresholds for infarction using contemporaneous CTP and 18F-fluoroethylfluoromazenil (FFM2) PET imaging, with the objective of deriving a CBF threshold for infarction after 3h of ischemia.

**Methods:** Cerebral ischemia was induced in the left hemisphere of 11 pigs by injecting endothelin-1 (ET-1) into the cortex through a burr hole in the skull. CTP scans were completed at baseline, 10, 30 then every then every 30 until 180min post ET-1 injection. If the CBF map at any time point showed reperfusion of the ischemic tissue then a second dose of ET-1 was administered. F-18 FFMZ was injected 2.5h after the first ET-1 injection and a 25min PET acquisition was started 25min post F-18 FFMZ injection. CBF maps from each CTP imaging time point were co-registered and a median CBF map was produced by taking the median value of each pixel. The median CBF maps, the PET images, average images from the baseline CTP study, and blood volume (BV) maps from the 10min post ET-1 CTP study were co-registered. ROIs were drawn on the cortex on the affected and contralateral side and superimposed onto all maps and images. Infarct pixels were identified on PET images as having ischemia-time dependent CBF thresholds for infarction using contemporaneous CTP and 18F-fluoroethylfluoromazenil (FFM2) PET imaging, with the objective of deriving a CBF threshold for infarction after 3h of ischemia.

**Results:** 6 of the 11 animals developed infarction with an average infarct volume of 1.4±0.38cm³. The optimal operating points of the ROC curves corresponded to CBF values of 14.2, 11.8, 18.9, 13.4, 13.9, and 19mL100g⁻¹min⁻¹. The average of these 6 values was calculated to find a 3h ischemia-time CBF threshold for infarction of 15.2±1.2mL100g⁻¹min⁻¹.

**Conclusions:** The 3h ischemia-time infarction CBF threshold of 15.2mL100g⁻¹min⁻¹ agrees well with the threshold of 12mL100g⁻¹min⁻¹ derived in a previous study (3). The ET-1 stroke model has the potential to derive CBF thresholds for infarction at other ischemia times by varying the time between the ET-1 injection and the start of PET imaging.

SP097.2 - Characterization of scatter factors in thyroid studies using a pinhole collimator by Monte Carlo Simulation.

**Author(s):** Adlin Lopez Diaz1, Sunay Rodriguez2, Angelina Diaz2, Aley Palau1, Juan Miguel Martin1
1Nuclear Medicine, Hospital Hermanos Ameijeiras, La Habana/CUBA, 2Physical Research, CEADEN, Havana/CUBA

To study the scatter factors during I-131 thyroid scintigraphic studies with a pinhole collimator (5mm hole) was developed a Monte Carlo (MC) simulation using GAMS code. First, to check the accuracy of the Monte Carlo model, simulated and measured data using a thyroid phantom were compared. The accuracy of the Monte Carlo model was verified by the good agreement between measured and simulated energy spectra and the maximum discrepancies of 2% in the counts/sec/MBq. Next, simulations to investigate scatter were performed for different tissue thickness between the thyroid and collimator (5-15mm). The image's scatter contribution was significant in the 5mm pinhole, being between 27-40%. On the basis of the separated scatter from direct count included in window energy spectra, a preliminary evaluation of multiple window energy correction methods was performed. For the simulated thyroid geometry with pinhole, the reduce inferior double energy window methods (15% on 364keV photopeak window) provides a reasonable correction for scatter. This study is the first approach; we recommend including real thyroid geometry with different thyroid depth-thickness and mass.

SP097.3 - Fluid Quantification Using Temporal Subtraction: Comparing Single to Dual-Energy Digital Chest Radiography

**Author(s):** Shaalia Sajja1, Samuel Richard2, Ali Urasni1, Fatima Urasni1, Megan Hickey3, David Foos1, Narinder Paul1
1Department Of Medical Imaging, Toronto general hospital, Toronto/ON/CANADA, 2Research And Innovation Labs, Carestream Health, Rochester/NY/UNITED STATES OF AMERICA, 3Brock University, Saint Catherines/CANADA

**Background:** Accurate quantification of thoracic water content is integral to assessing patient health in many disease states. Computed tomography (CT) provides tissue characterization and quantification but is generally not available for critically ill patients. Portable chest radiography (CXR) is often the only imaging modality available to inpatient patients; however, it has limited ability for estimating fluid content. Temporal subtraction (TS) provides temporally separated projections for quantifying differences in tissues over time, but performance is limited by image misregistration. Dual-energy (DE) CXR removes overlapping ribs and can reduce structures that are challenging to register. This research investigates the utility of portable TS-CXR and TS-DE-CXR for the detection and quantification of thoracic water.

**Evaluation:** Temporal subtraction of CXR images taken pre- and post-operation were used to determine change in fluid volume. The algorithm utilized the difference in x-ray attenuation signal between images to derive water thickness and to estimate the difference in water volume. 1-5 solid water blocks (40 ml each) were added (total volume of 200 ml) into the thoracic cavity of a static anthropomorphic chest phantom. CXR (120 kVp) and DE-CXR (60/120 kVp) were acquired after addition of each solid water block. A set of TS-CXR and TS-DE-CXR images were generated by subtracting the no-water image from the set of images with added water, from which volume estimates were derived. The experiment was repeated on a horizontally-moving phantom to simulate motion. Intensity-based rigid image registration was performed between pre- and post-op-
eration images followed by temporal subtraction. Image segmentation of the lung region was improved with TS-DE-CXR due to a clear demarcation between lung space and remaining thoracic region without the confounding impact of ribs. In addition, TS-DE-CXR had fewer misregistration artifacts resulting in improved registration performance and superior accuracy in estimation of water volume. The root mean squared error (RMSE) was 4.74 ml using TS-DE-CXR and 8.9 ml using TS-CXR. The range of error percentage was -7% to +2% with TS-DE-CXR and +6.3% to +16% with TS-CXR.

**Discussion:** TS-DE-CXR images are superior to TS-CXR images in providing accurate estimation of thoracic water volume. TS-DE-CXR has potential to enhance the diagnostic utility of DE-CXR for immobile patients.

**Conclusions:** TS-DE-CXR provides an accurate estimation of the volume of thoracic water. Further work will target validation of the TS-DE scheme on clinically acquired CXR images.

**SP097.4 - Quantitative low-kVp CT angiography in carotid artery imaging**

**Author(s):** Tingyu Mao1, Meili Yang1, Pengwei Wu1, Gaofeng Wang1, Xiangyang Tang2, Hongjie Hu1, Tianye Niu1

1Sir Run Run Shaw Hospital, Institute of Translational Medicine, Zhejiang University, Hangzhou/CHINA, 2Department of radiology, Emory University, Atlanta/GA/UNITED STATES OF AMERICA

Shading and streaking artifacts brought by beam hardening and photon starvation is commonly observed in low-kVp CT angiography (CTA) for carotid artery imaging. Image quality is thus significantly degraded and a faithful observation of carotid artery is impeded. In this paper, we propose a novel quantitative image postprocessing scheme to eliminate these artifacts. In shading correction, we follow general knowledge of the relatively uniform CT number distribution in one tissue component, and continuous and low-frequency shading artifact distribution in projection domain. Coarse image segmentation is first applied to construct an ideal template image where each structure is filled with the same CT number of that specific tissue. By forward projecting the difference between uncorrected CT image and the ideal template, we estimate the continuous and low-frequency shading error signal in projection domain low-pass filtering. An error map is then reconstructed using standard filtered back-projection algorithm from the error signal and added to the original image to correct for the shading artifacts. To suppress the increased noise and streaking artifacts, we first perform a texture extraction to estimate the noise distribution in the image and then incorporate the estimated noise variation into a nonlocal filtering method. The proposed scheme is evaluated in carotid CTA scan using a dual-source CT at 80 kVp, in which the shading and streaking artifacts can be successfully corrected by reducing the CT number error from 246 HU to 63 HU and spatial non-uniformity by a factor of 2.2, respectively. In the volume rendering generated from the corrected CT images, the visualization of carotid artery is improved substantially and comparable to that generated from a CTA scan at 140-kVp. The proposed method is implemented directly on the CT image without access to the raw projection data and is thus attractive for clinical application in low-dose CTA.

**SP097.5 - Evaluation of the ΔV Ventilation Calculation Method Using In Vivo XeCT Ventilation Data**

**Author(s):** Geoffrey G. Zhang1, Kujtim Latifi1, Kaifang Du1, Joseph M. Reinhardt1, Gary E. Christensen1, Kai Ding1, Vladimir Fegyelman1, Eduardo G. Moros1, Tingyu Mao1, Meili Yang1, Pengwei Wu1, Gaofeng Wang1, Xiangyang Tang1, Hongjie Hu1, Tianye Niu1

1Radiation Oncology, Moffitt Cancer Center, Tampa/UNITED STATES OF AMERICA, 2Human Oncology, University of Wisconsin School of Medicine and Public Health, Madison/WI/UNITED STATES OF AMERICA, 3Biomedical Engineering, University of Iowa, Iowa City/IA/UNITED STATES OF AMERICA, 4Radiation Oncology, Johns Hopkins University, Baltimore/MD/UNITED STATES OF AMERICA

Ventilation distribution calculation using 4DCT and deformable image registration (DIR) has shown promising potential in several clinical applications. This study evaluated the direct geometric ventilation calculation method, namely the ΔV method in which the local volume change is calculated geometrically using a deformation transformation, with Xenon-enhanced CT (XeCT) ventilation data from four sheep as the gold standard. The results are also compared to two other published ventilation calculation methods, namely the Jacobian and the Hounsfield Unit (HU) methods. The Diffeomorphic Morphons (DM) method was applied as the deformable image deformation (DIR) technique, and it was evaluated using the 4DCT data of the sheep with manually delineated landmarks in the end-expiration and end-inspiration phases in this study. Spearman correlation coefficient (SCC) and Dice similarity coefficient (DSC) were used for evaluation and comparison. The average target registration error of the landmarks by the DM method was 1.9 ± 1.5 mm. The average SCC with one standard deviation was 0.49 ± 0.13 with a range between 0.36 and 0.67 between the XeCT and ΔV ventilation distributions; 0.50 ± 0.13 (range 0.37 - 0.67) between the XeCT and the Jacobian ventilation distributions, and 0.31 ± 0.10 (range 0.23 - 0.44) between the XeCT and the HU ventilation distributions. The average DSC value for upper 30% ventilation volumes between the XeCT and ΔV ventilation distributions was 0.82 ± 0.03 with a range between 0.79 and 0.86, while for the upper 50% volumes, it was 0.70 ± 0.05 (range 0.64 - 0.77). The average DSC results between XeCT and Jacobian ventilation distributions were the same while between XeCT and HU they were 0.64 ± 0.05 for the upper 50% ventilation volumes (range 0.60 - 0.70) and 0.79 ± 0.03 for the upper 30% ventilation volumes (range 0.75 - 0.82). High ventilation volumes in ventilation distributions generated from 4DCT data were more accurate compared to low ventilation volumes. Ventilation difference introduced by deformable image registration errors improved with smoothing. The following figure shows the SCC values between the XeCT and the ventilation calculated using the three algorithms versus smoothing.

![Graph showing SCC values between XeCT and ventilation calculated using different methods.](image)

In conclusion, ventilation distributions generated using ΔV-4DCT and deformable image registration are reasonably accurate and therefore potentially useful in clinical practice. This evaluation study and previous reports support the use of ventilation calculated using 4DCT in clinical applications in areas such as radiation treatment planning and pulmonary function assessment.
The optimal tumour volume thresholds were 25 cm³, 42 cm³ and 20 cm³ for CMET, FLT and Gd-MRI respectively. There was a significant difference in survival time for tumour volumes above and below these thresholds for CMET-PET (p=0.02), but not for FLT-PET or Gd-MRI.

Conclusion: CMET-PET defined viable tumour volumes may discriminate between high and low survival times in post treatment glioma. FLT-PET or Gd-MRI defined volumes do not appear to be predictive of survival time. Further analysis with more subjects is required to verify the utility of method.

The dose deposited in air was estimated using a thimble ionization chamber at isocenter of the micro-CT scanner. We performed a histological study (H&E and Movat staining) to ensure no damage to the lungs resulted from the x-ray dose received.

Images were reconstructed with 0.05 mm voxel spacing using a FBP algorithm. The concentration of both contrast agents was calculated based on multi-energy equations. To improve the accuracy of the concentration calculations, we tested different denoising methods (on projections and the reconstructed volume).

**Results:**

The dose of each low- and high-energy scan was estimated to be 96.5 mGy and 91.2 mGy respectively. An example of the concentration of contrast agent map is shown Figure 1. Analysis was performed on the H&E stained histological sections to quantify the percentage of inflamed area over the total area of the lung section and the number of white blood cells present.

**Conclusion:**

High-resolution imaging of the vasculature and airways in rodents is achievable at low dose with contrast-enhanced micro-CT using subtraction methods. Because the K-Edges of the two most common CT contrast agents are very close, the multi-energy protocol was more difficult, and would benefit from advanced signal processing and reconstruction algorithms.

---

**SP097.8 - High-resolution micro-CT protocol for assessing lung ventilation and perfusion: image subtraction versus multi-energy analysis**

**Author(s):** Pierre Deman1, Samantha Tan1, Davood Karimi2, John Schiplow2, Rabab Ward2, Nancy L. Ford1

1Oral Biological And Medical Sciences, University of British Columbia, Vancouver/BC/CANADA, 2Electrical And Computer Engineering, University of British Columbia, Vancouver/BC/CANADA, 3Centre For High-throughput Phenogenomics, University of British Columbia, Vancouver/BC/CANADA

**Introduction:**

Micro-CT allows full-organ, high-resolution imaging of airways and lung vasculature in rodents when using contrast agents. Advantages include linearity of the measured signal versus the concentration of the contrast agent and co-registration between scans with high resolution leading to a good accuracy. We propose to compare a multi-energy imaging protocol and an image subtraction method to estimate the concentration of two contrast agents at an acceptable x-ray dose level for longitudinal monitoring.

**Methods:**

Respiratory-gated micro-CT imaging (CT120, Gamma Medica) was performed on 6 rats. Each rat was anaesthetized with isoflurane (1.5-2% in O2), intubated and mechanically ventilated. Low-energy images (50 kV, 63 mA, and 0.1 mm copper filtration) and high-energy images (120 kV, 40 mA, and 0.6 mm copper filtration) were obtained at baseline and post-injection of a vascular contrast agent (Binitio eXIA 160XL, 0.45 mL/ 100g). Rats were euthanized and ventilated with xenon while images were obtained with both the low- and high-energy protocols. The spectrum of each protocol was evaluated using HVL measurements and by simulation with the Spetkr freeware.
Abdominal aortic aneurysm (AAA) is a cardiovascular disease occurring when the aorta becomes weak and develops a balloon expansion in its wall. This balloon diameter can reach sizes up to 4 times the normal aortic diameter, with the diameter enlarging at rates of 0.2–1.0 cm/year. Ruptured aneurysm leads to death in 78% – 94% of diseased aortas [1]

Aneurysm rupture is a biomechanical event that occurs when the mechanical stresses in the wall of the aorta exceed the failure strength of the aortic tissue [2].

In medical practice, when the maximum diameter of AAA exceeds 5 cm it is considered at risk of rupture. Surgical repair is usually not considered until the diameter reaches at least 5 cm. However, it is frequently observed that AAAs with diameters less than 4 cm can rupture which raise the need of finding a more reliable method to assess rupture risk.

The role of the intraluminal thrombus (ILT) which exists in more than 75% of AAA was examined using variable thickness and material properties of the thrombus. The role of the ILT has been experimentally examined in number of studies [4; 5; 6].

ILT with variable thicknesses were used here to examine the effect of ILT on wall stresses compared with AAA without ILT.

High-frequency ultrasound (10-100 MHz) is particularly sensitive to small vascular structures that are close in size to the ultrasound wavelength (15-150 mm). The ability to rapidly determine the degree of vascularization in small animals in vivo would provide a useful characterization tool for regenerative medicine. The objective of this study was to determine if direct ultrasonic measurements in the 10-100 MHz range could be used as a vascularization assay for small animals and tissue specimens. To accomplish this, a study was performed at the Ludwig Boltzmann Institute for Experimental and Clinical Traumatology (Vienna, Austria), where the femoral artery in one hind limb of each of sixteen mice was ligated and tested for eight days. Eight of the ligated limbs were treated with vascular endothelial growth factor (VEGF, “treated”) while the remaining eight ligated limbs were not treated (“untreated”). All of the ligated limbs were then allowed to grow ischemic. The unilateral limbs were controls. Pitch-catch and pulse-echo measurements were acquired using a 50-MHz immersion transducer (Olympus NDT, V358-SU), a high-frequency square-wave pulser/receiver (UTEX, UT340), and a 1-GHz digital oscilloscope (Agilent, DSOX3104A). The ultrasonic transducers were coupled to the limbs using glycerol, and triplicate waveforms were acquired from each limb every other day. The ultrasonic parameters analyzed were wave velocity and peak density. Peak density is the number of peaks and valleys in the ultrasonic spectrum between 20–80 MHz, and provides a measure of spectral complexity. In two hospital studies on breast cancer surgical margins, peak density was demonstrated to be sensitive to microstructural changes in tissue due to both benign and malignant processes. The mice were also evaluated with laser Doppler interferometry (LDI), multispectral optoacoustic tomography (MSOT), micro-CT (computed tomography), and histopathology. The results indicated that ultrasonic signals from untreated limbs displayed a steady decrease in wave velocity over the test period as compared to the treated limbs. Peak density displayed no trends for either untreated or treated limbs. The peak density results were consistent with the other evaluation methods, which primarily reveal changes in tissue microstructure and showed no significant differences between the untreated and treated limbs. In contrast, wave velocity is sensitive to the stiffness of the tissue, a material property that is not measured by the other methods. The decrease in wave velocity for the untreated limbs indicates a softening of the muscle tissue, possibly due to inflammation or edema, whereas the decrease and then return to normal for the treated limbs indicates recovery of the tissue. The high-frequency ultrasound may therefore have detected effects due to ischemia and revascularization that were hidden to LDI and histopathology (MSOT and micro-CT data have yet to be analyzed). The study results indicate that high-frequency ultrasound, in particular wave velocity measurements, may provide an added dimension to small animal imaging methods for detecting revascularization. The method is currently being expanded to include high-resolution imaging.

In the 21st century the medical field has majority of its equipment coming in contact with blood is manufactured from plastic polymers. This causes a major concern, where exposure may result in undesirable protein–material interactions that can potentially trigger deleterious biological processes such as thrombosis. To address this problem, we have developed an ultrathin antithrombogenic coating based on monoethylene glycol silane surface chemistry. The strategy is exemplified with several polymers including: polycarbonate and poly (vinyl chloride) -plastic polymers increasingly employed in the biomedical industry. The various straightforward steps of surface modification were characterized with X-ray photoelectron spectroscopy supplemented by contact angle goniometry. Anti-thrombogenicity was assessed after 2,5,10 and 60 min exposure to whole human blood dispensed at a shear rates of 300, 900, 1000 and 1500 s⁻¹. Remarkably, platelet adhesion, aggregation, and thrombus formation on the coated surface was greatly inhibited on all shear rates and both surfaces (>92% decrease in surface coverage) compared to the bare substrate and, most importantly, nearly nonexistent.
ABSTRACTS | IUPESM 2015 WORLD CONGRESS ON MEDICAL PHYSICS & BIOMEDICAL ENGINEERING

RESULTS

The architecture of collagen fibers ranged from highly organized and parallel fibers at the periosteum, to loosely woven strands in muscle attachment sites, and then to irregular and thin fibers at the perimysium (Fig. 1). The elastin fibers were spring-like, short, and of irregular architecture and arrangement. Elastin fibers were also primarily abundant in the major centroidal axis, and formed a 3D mesh in the z-stack (Fig. 1).

DISCUSSION

Collagen fibers are mechanically robust, flexible and able to resist tensile loading. The network of fasciae, comprising of mostly wavy collagen fibres branching from the perimysium to the periosteum (Fig. 1), suggest that fascia may be mechanically significant in supporting tissue structures, e.g. preventing distension between the muscle and bone.

Since centroidal axes correlate within 5% of anatomical axes, variations in the arrangement and composition of elastic fibers can be associated with its function. Hence the abundance of elastin in the posterior major CA may be functionally associated with the prevalence of greater muscle bulk in its corresponding anatomical aspect.

CONCLUSIONS

Therefore, by harnessing the “smart” properties of nature’s own biological materials and applying a bottom-up approach to engineering novel materials, we aim to facilitate the development and engineering of functional and biomimetic materials. First applications are ongoing for development of novel functional textiles to prevent and...
treat lymphoedema as well as to provide an optimal interface (liner sleeve) for trans-tibial and femoral prostheses.

SP098.5 - Vascular endothelial cell adhesion and hemocompatibility of biochemically- and topographically-modified poly(vinyl alcohol)

Author(s): Marie F. Cutongco1, Deirdre E.J. Anderson2, Monica T. Hinds3, Evelyn K.F. Yim4
1Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE, 2Biomedical Engineering, Oregon Health & Science University, Portland/UNITED STATES OF AMERICA

Currently available synthetic small diameter vascular grafts used for bypass or replacement of native arteries fail within the first 10 years. The lack of mechanical properties matching native arteries, thromboresistance and capacity to stimulate in situ endothelialization prevent the long-term application of small diameter vascular grafts. Thus, there is a critical need for new synthetic small diameter vascular grafts that can achieve compliance, hemocompatibility and endothelialization. Poly(vinyl alcohol) hydrogel (PVA) is an excellent candidate for vascular grafts due to its tunable mechanical properties, high water content and high tensile strength. Yet the bio-inерт-ness of PVA must be addressed to improve endothelialization in situ. Both biochemical and topographical modifications have been used to stimulate specific vascular endothelial cell behaviours on synthetic materials by mimicking the physiological cellular niche. Thus, we hypothesize that the modification of PVA with both biochemical and topographical modifications can provide a hemocompatible microenvironment that stimulates endothelialization. PVA modified by the immobilization of fibronectin, RGDS peptide, and cyclic RGD (cRGD) peptide showed slight increase in the adhesion of human umbilical vein endothelial cells (HUVECs) while PVA modified with immobilized heparin showed significant decrease in the endothelial cell adhesion. The cRGD modified PVA did not exhibit any significant change in platelet adhesion, activation and morphology when compared with unmodified PVA in an in vitro hemocompatibility assays using LDH assay, microparticle release percentage and scanning electron microscopy, respectively. Using solvent casting, unmodified and cRGD-modified PVA were incorporated with micro-gratings or microlens topography. Combination of cRGD and micro-gratings or microlens topography on PVA showed significant increase in endothelial cell viability compared with unpatterned and unmodified PVA. Platelet adhesion on all PVA modified with microgratings was comparable with unpatterned and unmodified PVA. PVA with microlens topography significantly increased platelet adhesion, while PVA with both convex and cRGD modification showed no difference with unpatterned and unmodified PVA. Platelets also changed from the fibrous, activated phenotype on PVA with microgratings or microlens to round and less active phenotype on PVA with both cRGD and topography (Figure 1). The in vitro vascular endothelial cell adhesion tests and hemocompatibility tests demonstrated that modification of PVA with both biochemical and topographical cues may serve as an excellent surface for hemocompatible vascular grafts with enhanced endothelialization.

Figure 1. Platelet adhesion on PVA surfaces modified with cRGD and topography.

Interaction between magnetic field and living systems is inevitable; in fact, we are immersed in an ocean of magnetic field due to the magnetic field of the earth and the technology developments. Interaction between magnetic field and living systems is inevitable; in fact, we are immersed in an ocean of magnetic field due to the magnetic field of the earth and the technology developments, this one already have medical applications, currently, the pulsed electromagnetic fields (PEMF) are an alternative option for the treatment of some mental illness as the depression or schizophrenia. In order to have estimation of the side effects from PMF and drugs used for treat this kind of disorders. In this work, it is presented a comparison of the effects of imipramine, a drug for the treatment of depression, and the effects of PMF on cells from the line SHSY5Y, which provide us a representative model of neuronal tissue. The assays were done in both ways, the separately effects and the jointly effects. The imipramine at high dosage for a short period (120 mg/mL, for 20 min) shows cell damage on both, the morphology and the metabolism. Meanwhile, the PMF (50 Hz, 7 mT for 8 h) shows a cell proliferation and a decrease of their metabolism. The jointly assay indicates that the PMF balances the morphological negative effects from imipramine. In the long term these results can impact a therapy that may be more efficient. However, more research is needed in this area

SP012.2 - Porous bio-SiC ceramics from wood: approaching new medical implants

Author(s): Oleksandr Gryshkov1, Nikolai Klyui2, Volodymyr Temchenko2, Vitalii Dubok2, Vitalii Kiselyov2, Alexander Belyaev2, Birgit Glauschmacher1
1Leibniz University Hannover, Institute for Multiphase Processes, Hannover/GERMANY, 2V. Lashkaryov Institute Of Semiconductor Physics, National Academy of Science of Ukraine, Kyiv/UKRAINE, 3I. Frantsevich Institute For Problems Of Materials Science, National Academy of Science of Ukraine, Kyiv/UKRAINE
Introduction

Silicon carbide ceramics (SiC) are porous structures derived from different wood sources. The porosity and pore size of such ceramics may repeat the structure and porosity of specific bones in human body. Additional coating of SiC ceramics with hydroxyapatite (HA) and tricalcium phosphate (TCP) using a novel gas-detonation deposition method (GDD) could be advantageous with regard to bone replacement. This work investigates the porosity of SiC ceramics and explores the method to obtain bioactive surfaces.

Methods

Biomorphic porous SiC ceramics were synthesized using forced infiltration with liquid silicon of carbon matrices derived from different hardwood precursors (Hornbeam, Sapele, Tilia and Pear). This process involves impregnation of carbon matrices by silicon and synthesis of SiC ceramics. The porosity of SiC ceramics was analyzed based on 10 images taken using a Carl Zeiss Stereo Discovery.V12 microscope. The HA and TCP coatings were obtained utilizing the GDD method by transporting the powder using a detonation wave at high velocities [1]. The surface morphology of SiC ceramics and deposited coatings was characterized using a scanning electron microscope (SEM).

Results

The GDD method allowed obtaining high-adhesive and structurally perfect bioactive coatings onto SiC ceramics derived from different wood sources (Figure 1). The surface morphology of synthesized SiC ceramics was regular throughout the surface. The smallest pores were observed for SiC ceramics synthesized from Tilia (27.2±10.1 μm), whereas Sapele-derived ceramics yielded the pores with a mean size of 131.2±41.1 μm. The calculated highest porosity was inherent to Hornbeam-derived SiC ceramics (45.3±3.4%). Moreover, the porosity was greater for more dense SiC ceramics and was also dependent on mean pore size.

Acknowledgments

The authors acknowledge the exchange program with East European Countries funded by DAAD and are looking for further funding of the project.

References

Conclusions and outlook

In this study, the bio-SiC ceramics synthesized from different wood precursors were characterized for surface morphology, porosity and pore size distribution; whereas the GDD method was used to generate bioactive HA and TCP coatings. The advantage of these ceramics is that the porosity and pore size can be optimized for different bones by varying the initial wood source. In turn, application of biocompatible and bioactive surfaces onto SiC ceramics could accelerate bone substitution.
SP099 - SPECIAL SESSION: Current situation of dosimetry in radiology and radiation protection

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP099.1 - Current situation of dosimetry in radiology and radiation protection

Author(s): Madan M. Rehani1, Harry Delis2, Pablo Jimenez3, Joanna Izewska4

Radiation protection in medicine essentially poses dosimetry issues pertaining to patient dosimetry with some aspects of occupational dosimetry mainly relating to the lens of the eye. Dosimetric measurements in diagnostic radiology are required for the establishment and use of guidance levels, for the assessment of equipment performance and for comparative risk assessment. However, since radiology involves a diverse range of examination types, from simple projection radiography to advanced cross-sectional imaging, several dose quantities have been developed and have been well worked out by IAEA and ICRU. Further, data on the status of patient doses in different radiology procedures enable comparisons with diagnostic reference levels. The reference dose quantities have been well deciphered by the IAEA and ICRU. Some information about patient doses has become available through multi-national studies on patient doses to adults and children in CT, image guided interventional procedures (as relatively high dose procedures), as well as in mammography and conventional radiography of other organ systems. Image quality has been considered in some situations. Important findings include frequent lack of optimization in paediatric CT. There is a need for coordinated actions by different international organizations and professional bodies to improve optimization of protection which requires management of the radiation dose commensurate with the medical purpose. Particular to medical imaging, this equates to the lowest possible dose necessary to acquire diagnostic quality images. Regarding occupational radiation protection, cataract risk is important among staff in interventional suites. Currently, there is near absence of monitoring of eye lens doses and actions are needed to develop and implement practical methods for eye lens dosimetry. This issue has attained greater significance granted the drastic reduction of the occupational eye lens dose limit from 150 mSv/year to 20 mSv/year, recommended by the International Commission on Radiological Protection (ICRP) and adopted in the new BSS. The IAEA has been working on promoting and supporting best practices in dosimetry, including traceability of measurements to the International System of Measurement, and strengthening the medical physics capacity throughout the world since the early sixties. As it represents one of the main resources for the medical physicists, and often, especially in developing countries, the only one, work is done in producing guidelines on dosimetry in diagnostic radiology, (Dosimetry code of Practice (TRS-457), Dosimetry for Paediatric Patients (HIPS-24), Dosimetry of Wide beam CT (HHR-5)) to support dosimetry in the clinical environment. Therein exists a role for international organizations to promote and support actions on patient and staff dosimetry to improve both patient and occupational safety. This joint session will discuss modalities of cooperation. This joint session will address the current and future activities and areas for cooperation in the field.

SP100 - Dose Optimization: Focus on DRLs

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP100.1 - A Contribution to the Establishment of Diagnostic Reference Levels in Computed Tomography in Brazil

Author(s): Lucas D.L. Narciso, Ana M. Marques Da Silva, Nathan W. Lima, Caroline M. Dartora

Faculdade De Fisica, PUCRS, Porto Alegre/BRAZIL

Diagnostic reference level is important to guarantee dose optimization, and can be defined nationally, regionally or locally, using dose descriptors, such as volumetric computed tomography (CT) dose index (CTDIvol, mGy) and dose-length product (DLP, mGy.cm). The aim of this work is to present the local DRL values for a CT department located in Porto Alegre, Brazil, intending to determine, in the future, national and regional DRL. For this purpose, retrospective data have been collected and analyzed, from head, chest and abdomen non-contrast CT adult (>15 years old) and pediatric (<15 years old) exams. The DRL values have been compared to those described on previous national studies from UK, US, Germany and Switzerland. The results are shown in the following table. These values are similar to the DRLs from Germany, UK, US and Switzerland. The present study is the first of its kind to determine the DRL for scanners operating in the south region of Brazil. Similar studies in other regions of Brazil are necessary in order to establish a National Dose Reference Level.

Increasing numbers of Computed Tomography (CT) scanners, examinations and CT’s relatively higher patient dose (compared to planar x-ray) have resulted in increased focus on the modality, both in Canada and world-wide. The key pillars of safe imaging, justification and optimization, are becoming especially important to follow. It follows that as CT use increases; protocol optimization (reduction of patient dose while maintaining necessary image quality) is an ever crucial part in reducing patient dose. A widely endorsed and adopted method is the establishment of diagnostic reference levels (DRLs) – typically accepted as the 75th percentile of CTDIvol and/or DLP distributions for a given patient exam type/indication – which help identify protocols that may benefit from further investigation and any necessary dose reduction initiatives.

The establishment of DRLs requires a significant and representative pool of scanning practice data – Canada’s National CT Survey collected data from 381 CT units across the country via distributed survey booklets (1 per CT unit) divided into four (4) sections: General CT information (e.g. Vendor/Model), Routine Protocols (as available), Individual Patient data (as applied) and limited CTDIvol measurements. The resultant electronic database includes a large cross-section of general vendor/model data, 2896 routine protocol samples (3494 sequences), 18 985 individual (actual) patient exam samples (24 280 sequences) and some CTDIvol measurements.

The national survey database covers seven (7) common exam types (Table 1) and is a significant step toward establishment of national DRLs which will help support protocol optimization efforts. Of course, prior to calculation of any reference levels, applied data quality assurance is essential. In our experience, key issues had to be addressed: (i) booklet, patient and sequence numbering mistakes were vetted by an iterative algorithm to verify their accuracy and association (ii) CT vendor/model names were inconsistent, thus a standard convention was applied to facilitate future analysis (iii) incomplete patient mass, potentially limited DRL sample sizes. Implementation of iterative, logical algorithms allowed AP and LAT measurements to act as a surrogate, increasing representative sample numbers (iv) Other, incomplete exam descriptors (contrast/ non, modulated/ fixed etc.) presented potential issues, but similar iterative, logic algorithms were also applied to help “complete” samples. E.g. string based search/flag clarification.

Ultimately, the large national sample will provide DRLs, based upon dose metrics for 7 common CT examinations, supporting local optimization efforts and radiation protection of patients across Canada.
Methods

After undergoing $^{99m}$Tc-HDP bone examinations, 143 patients were studied. Dose rates [H*($^{10}$)] were measured from the mid thorax after radiopharmaceutical injection and after bone scan with a Geiger dose-meter at 0.1, 0.5, and 1.0 m. A number of different scenarios were carried out during absorption period and after leaving the Department of Nuclear Medicine. A dose of 1 mSv/year was used upon which restrictions should be imposed. The results were evaluated using the 95th percentile.

Results

The injected activity [median (min-max)] was 744 (370-844) MBq while absorption time and time for imaging procedure were 160 (80-280) and 55 (25-117) minutes.

The median dose rates measured at the three distances were 112.4, 29.8 and 11.5 μSv/h after the $^{99m}$Tc-HDP administration and 29.9, 9.8 and 4.3 μSv/h after the image scan.

The absorbed doses were:

During an incorporation interval of 4 hours, the absorbed dose to which a subject could be exposed to due to contact with an injected patient in the waiting room would be 543, 134, and 52 μSv at a distance of 0.1, 0.5, and 1.0 m.

Conclusions

The people with higher doses are those who are in close contact with the patient (the escort and the spouse/partner). Nevertheless, the imposition of restrictions is not needed. However depending on the workload of the physicians, some restrictions might be required. Furthermore, the dose received in the waiting room from an injected patient is comparable to a bone scan.

TRACK 11: NEUROENGINEERING, NEURAL SYSTEMS

SP101.1 - Biological Targets of Seizure Therapy in Major Depressive Disorder using EEG Microstate Analysis

**Author(s):** Sravya Atturi1, Willy Wong1, Daniel M. Blumberger2, Zafiris J. Daskalakis2, Faranak Farzan2

1Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA, 2Centre for Addiction and Mental Health, Toronto/ON/CANADA

**Introduction:** Understanding the exact mechanism of action of electroconvulsive therapy (ECT) can support the optimization of alternative treatments such as magnetic seizure therapy (MST) towards high efficacy and less side effects. Recent evidence suggests that major depressive disorder (MDD) may be associated with impaired brain functional connectivity and that ECT may achieve high efficacy in treatment-resistant MDD by normalizing abnormal neural connectivity. Resting-state EEG microstate analysis is one promising method that classifies global neural activity into discrete and short periods (80-120ms) of quasi-stable functional brain topographic maps (known as microstates) that change over time to represent dynamic states of global functional connectivity. **Methods:** For this study, pre- and post-treatment 60-channel resting state EEG data of 14 MDD patients (7 responders and 7 non-responders) receiving ECT and 13 MDD patients (3 responders and 10 non-responders) receiving MST were obtained from the Temerty Centre at the Centre for Addiction and Mental Health. The criterion for treatment response was a minimum of 50% improvement in the Hamilton Depression Rating Scale (HAM-D) score. Three main analyses were conducted with the data: (a) Spectral analysis was performed to determine whether previous findings of ECT-induced EEG slowing could be replicated. (b) Microstate analysis was performed to assess seizure therapy-related changes in the dynamic states of global functional connectivity. Four microstate classes were identified and four features were calculated for each class: (i) frequency of occurrence, (ii) transition time between each class, (iii) average duration and (iv) coverage time (fraction of total time covered by a class). (c) Finally, correlation analyses were performed to examine whether baseline microstate and power features could predict response (change in HAMD score) to seizure therapy. **Results:** (a) Similar to previous findings, frontal delta (0.5-3.5Hz) and midline theta (4-7Hz) were found to be significantly larger in ECT responders than non-responders. However, this effect was not observed in MST treatment. (b) Also following ECT treatment (but not MST), the frequency of appearance of each microstate class was significantly lower in responders than non-responders (p = 0.03). The transition time between two consecutive microstate classes increased in responders but did not significantly change in non-responders (p = 0.04). The average duration of all four microstate classes was significantly longer for both responders and non-responders (p = 0.001). A change in HAMD score was associated with an increased coverage time of class C (r = 0.56, p = 0.03) and a decreased coverage time of class A (r = -0.62, p = 0.02). (c) Lastly, the frequency of microstate class C pre-treatment was correlated with reduced response to ECT (r = -0.61, p = 0.02) and an increased response to MST (r = 0.54, p = 0.05). **Conclusion:** Preliminary results suggest that microstate features from resting-state EEG data may provide new and predictive information about the effect of seizure therapy in MDD and should be further explored with larger datasets.

SP101.2 - Magnetic Seizure Therapy for Treatment Resistant Depression: Insights from TMS-EEG Measures

**Author(s):** Yinning Sun1, Faranak Farzan2, Daniel M. Blumberger2, Willy Wong1, Zafiris J. Daskalakis2

1Ibbme, University of Toronto, Toronto/ON/CANADA, 2Psychiatry, University of Toronto, Toronto/ON/CANADA

Magnetic seizure therapy (MST) is a potential therapeutic option for treatment resistant depression (TRD) that has shown comparable efficacy and less side effects relative to electroconvulsive therapy. Since cortical inhibition is abnormal in TRD patients, measures of inhibition from combined transcranial magnetic stimulation and EEG (TMS-EEG) may further the understanding of MST treatment and provide predictors of its treatment response. Thirty-three TRD patients were recruited in this TMS-EEG study. Before a course of MST treatment, responses from single pulse TMS over the motor cortex and dorsolateral prefrontal cortex (DLPFC) were recorded using EEG. The peak value of the TMS evoked potential near 100 ms (i.e. N100) was computed for each patient and correlated with changes in clinical measures of depression (Hamilton Depression Rating Scale, HDRS-24) and suicidality (Scale of Suicidal Ideation, SSII) collected before and after treatment. For DLPFC stimulation, the N100 value over the frontal electrodes was significantly correlated with a decrease in the HDRS-24 (max at F2, R = -0.51, p = 0.006) and SSII (max at F6, R = -0.61, p = 0.001) values. Moreover, when patients were grouped into responders and non-responders based on SSII change (responder: 50% or more decrease from baseline), the N100 value can predict the label with 80% sensitivity and 89% specificity. These results were not found for motor cortex stimulation. Correlation and classification results suggest that frontal N100 values resulting from TMS stimulation of the DLPFC can be a potential predictor of clinical response to MST treatment for resistant depression.

SP101.3 - Deep Transcranial Magnetic Stimulation Using Figure-of-Eight and Halo Coils

**Author(s):** Mai Lu1, Shoogo Ueno2

1Key Lab. Of Opt-electronic Technology And Intelligent Control Of Ministry Of Education, Lanzhou Jiaotong University, Lanzhou/CHINA, 2Department Of Applied Quantum Physics, Graduate School Of Engineering, Kyushu University, Fukuoka/JAPAN

Transcranial magnetic stimulation (TMS) is a technique for noninvasive stimulation of the human brain, which has become a major tool in brain research and, potentially, a promising treatment for various neuro-behavioral disorders. Recently, interests in stimulating deeper cortical, subcortical and limbic areas have arisen and have become an active research topic in TMS, because several studies show that activation of deeper prefrontal and limbic regions may increase the antidepressant effect. The Halo coil, a large circular coil being placed around the head was developed for deep transcranial magnetic stimulation(dTMS). It was shown that the Halo coil working with a typical round coil at the top of the head can increase the fields at depth in the brain. The present study was to study the field characteristics of a figure-of-eight coil (Fo8) which was placed at the left dorsolateral prefrontal cortex (DLPFC) working with a Halo coil which was parallelly placed with that of Fo8 coil (Fo8-Halo assembly) as shown in Fig. 1. The same pulse currents with amplitude of I=5 kA and working frequency 2381 Hz was fed into each of the coils. A 3D realistic human head model with 1 mm resolution has been employed in this study. We have calculated the magnetic fields, electric fields and current density in head tissues by using impedance method. Figs. 2(a)-(c) show the variation of induced electric field in the cross section of the head model at 80 mm slice (coronal) for Fo8, Halo and Fo8-Halo assembly coils, respectively. It was observed that the field intensity in deep brain regions have been improved by Fo8-Halo assembly coil. Results suggest that the conventional Fo8 coil can be applied for dTMS by working with a...
Halo-coil for DLPFC stimulation.

Cortical theta burst stimulation (TBS) could modulate motor plasticity via long-term potentiation/depression (LTP/LTD)-like mechanisms and enhance motor performance, which makes TBS a potential non-invasive therapy for motor deficit diseases such as Parkinson’s disease (PD). In our previous rodent study, we had demonstrated that long-term cortical electrical stimulation (CES)-TBS protocols were capable to regulate motor-evoked potentials (MEPs) and enhance motor performance in chronic PD rats. However, the immediate effect of CES-TBS on motor performance in awake, freely moving rat was constrained by wired electrode and stimulators. Since CES excited all types of neurons surrounding the electrode in cortex, it is difficult to differentiate the effect of TBS on specific neural circuit that responds to motor plasticity and performance. It is also known that LTP/LTD occurred dominantly at glutamatergic synapse. The aim of this study is to apply the cell type-specific optogenetic TBS scheme in M1 could be an efficient therapy scheme for neural disorders like PD via targeting specific neural circuit. Ongoing project is working toward the observation of animal behavior during and after optogenetic-TBS treatment of free-moving rat.

Our results showed that the local field potentials were recorded in high fidelity and responded well to the optical stimulation. The averaged MEPs amplitude were increased after optogenetic TBS treatment. The observations indicate that motor plasticity was modulated resulting from TBS on glutamatergic neurons in M1. However, there was no significant change in cortical excitability revealed from LFPs. In summary, our results suggested that LTP/LTD-like effects induced by cortical TBS treatment might be located at glutamatergic projections downstream of M1. The modulation of motor plasticity using cell type-specific optogenetic TBS scheme in M1 could be an efficient therapy scheme for neural disorders like PD via targeting specific neural circuit. Ongoing project is working toward the observation of animal behavior during and after optogenetic-TBS treatment of free-moving rat.

Functional electrical stimulation (FES) is used to artificially induce contractions in paralyzed muscles as neuroprosthesis to substitute lost motor functions, in individuals with spinal cord injury or other neuromuscular impairments. The dynamic response of muscles to FES is an integral component of closed-loop controlled neuroprostheses such as neuroprostheses for standing balance. This study aimed at identifying the dynamic response of ankle muscles to FES in a standing posture with FES as an input and the exerted isometric ankle torque as an output using both first-order and critically-damped second-order models.

Thirteen healthy subjects participated in the experiment. Each subject stood on a standing frame with his/her extended knee and hip mechanically locked. The ankle plantarflexors and dorsiflexors were separately stimulated bilaterally through surface electrodes using a programmable functional electrical stimulator (Compex Motion II, Compex SA, CH). The subject’s feet were fixed firmly to the footplates connected to a torque transducer (TS11-200, Durham Instruments, DE) that recorded the exerted isometric ankle torque. The stimulus waveform was rectangular with pulse frequency of 20Hz and pulse duration of 0.3msec. The pulse amplitude was modulated on sinusoids between 20mA and 60mA at frequencies of 0.07, 0.15, 0.3, 0.75, and 1.2Hz. The sinusoids of FES pulse amplitude and fitted to the generated ankle torque curve were considered as input and output, respectively. A Bode diagram was plotted based on the five obtained amplitude gains and phase lags between the input and output. The first-order and critically-damped second-order linear models were fitted to the diagrams and their parameters were estimated for each subject.

**ABSTRACTS | IUPESM 2015 WORLD CONGRESS ON MEDICAL PHYSICS & BIOMEDICAL ENGINEERING**

**SP101.4 - Optogenetic Stimulation and Wireless Cortical Recording in Modulating Motor Plasticity and Performance of Free-Moving Rat**

**Author(s): Chun-Wei Wu, Cho-Han Hsieh, Jia-Jin J. Chen**

Biomedical Engineering, National Cheng Kung University, Tainan/TAIWAN

Cortical theta burst stimulation (TBS) could modulate motor plasticity via long-term potentiation/depression (LTP/LTD)-like mechanisms and enhance motor performance, which makes TBS a potential non-invasive therapy for motor deficit diseases such as Parkinson’s disease (PD). In our previous rodent study, we had demonstrated that long-term cortical electrical stimulation (CES)-TBS protocols were capable to regulate motor-evoked potentials (MEPs) and enhance motor performance in chronic PD rats. However, the immediate effect of CES-TBS on motor performance in awake, freely moving rat was constrained by wired electrode and stimulators. Since CES excited all types of neurons surrounding the electrode in cortex, it is difficult to differentiate the effect of TBS on specific neural circuit that responds to motor plasticity and performance. It is also known that LTP/LTD occurred dominantly at glutamatergic synapse. The aim of this study is to apply the cell type-specific optogenetic stimulation and wireless recording of local field potentials (LFPs) to reveal the functional roles of glutamatergic neuron in motor plasticity of freely moving rat.

CaMKIIalpha promoter driven channelrhodopsin-2 (CaMKIIalpha-ChR2) was expressed in glutamatergic pyramidal neuron in primary motor cortex (M1). Optogenetic stimulation was achieved using blue laser guided by optical fiber, which was connected by a rotary joint to allow freely rotation. Then the fiber was connected to optical cannula implanted on skull. Optical cannula was homemade of a stainless tube containing a short segment of optical fiber inside. Both ends of the fiber were polished to minimize optical scattering when Laser was emitted into cortex. Stainless tube of the optical cannula was functioned as cerebral electrode to collect electrophysiological signal. Brain biopotentials were then amplified, band-pass filtered and converted to a frequency modulated radio-frequency (RF) signal sent by a small and light (2.7 g) wireless transmitter headstage connected to stainless tube. RF signals were transmitted to the host unit and was demodulated into analog signal and sampled by DAQ card. Optogenetic evoked potentials were analyzed and displayed using average calculation during and after optogenetic TBS treatment.

In summary, our results suggested that LTP/LTD-like effects occurring from TBS on glutamatergic neurons in M1. However, there was no significant change in cortical excitability revealed from LFPs. Our results showed that the local field potentials were recorded in high fidelity and responded well to the optical stimulation. The averaged MEPs amplitude were increased after optogenetic TBS treatment. The observations indicate that motor plasticity was modulated resulting from TBS on glutamatergic neurons in M1. However, there was no significant change in cortical excitability revealed from LFPs. In summary, our results suggested that LTP/LTD-like effects induced by cortical TBS treatment might be located at glutamatergic projections downstream of M1. The modulation of motor plasticity using cell type-specific optogenetic TBS scheme in M1 could be an efficient therapy scheme for neural disorders like PD via targeting specific neural circuit. Ongoing project is working toward the observation of animal behavior during and after optogenetic-TBS treatment of free-moving rat.

**SP101.5 - Identification of calf muscles response to functional electrical stimulation as linear models**

**Author(s): Hossein Rouhani1, Michael Same2, Ya Q. Li2, Kei Masani2, Milos R. Popovic2**

1Lyndhurst Centre, Toronto Rehabilitation Institute - University Health Network, Toronto/CANADA, 2Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA

Functional electrical stimulation (FES) is used to artificially induce contractions in paralyzed muscles as neuroprosthesis to substitute lost motor functions, in individuals with spinal cord injury or other neuromuscular impairments. The dynamic response of muscles to FES is an integral component of closed-loop controlled neuroprostheses such as neuroprostheses for standing balance. This study aimed at identifying the dynamic response of ankle muscles to FES in a standing posture with FES as an input and the exerted isometric ankle torque as an output using both first-order and critically-damped second-order models.

Thirteen healthy subjects participated in the experiment. Each subject stood on a standing frame with his/her extended knee and hip mechanically locked. The ankle plantarflexors and dorsiflexors were separately stimulated bilaterally through surface electrodes using a programmable functional electrical stimulator (Compex Motion II, Compex SA, CH). The subject’s feet were fixed firmly to the footplates connected to a torque transducer (TS11-200, Durham Instruments, DE) that recorded the exerted isometric ankle torque. The stimulus waveform was rectangular with pulse frequency of 20Hz and pulse duration of 0.3msec. The pulse amplitude was modulated on sinusoids between 20mA and 60mA at frequencies of 0.07, 0.15, 0.3, 0.75, and 1.2Hz. The sinusoids of FES pulse amplitude and fitted to the generated ankle torque curve were considered as input and output, respectively. A Bode diagram was plotted based on the five obtained amplitude gains and phase lags between the input and output. The first-order and critically-damped second-order linear models were fitted to the diagrams and their parameters were estimated for each subject.
Correlation coefficient and RMS error between the experimental and fitted data were calculated to evaluate the fitting. Two-way ANOVA (factor1: first-order or second-order models, factor2: plantarflexors or dorsiflexors) revealed that both models were not significantly different in correlation coefficient and RMS error for both amplitude gain and phase lag (p>0.6) (Table 1). The inter-subject variability was expressed as CV (=100×SD/mean). The CV of the time constants obtained by the second-order model for plantarflexors (18.1%) was significantly smaller than the CV of the time constants obtained by the first-order model (79.9%) (F-test, p<0.001). Therefore, the time constant obtained by the critically-damped second-order model was more consistent among subjects for plantarflexors. This finding should be considered in the design of closed-loop controlled neuroprostheses when immediate torque generation is expected. In the future, the physiological interpretation and nonlinear components of this modeling should be further investigated.

SP101.6 - Establishment of Real Human Head Conductivity Model with Ventricular Structure used in TMS Simulation Study

**Author(s):** Chen Zhao, Huanhuan Cheng, Zhipeng Liu, Tao Yin

Institute Of Biomedical Engineering, Chinese Academy of Medical Sciences, Tianjin/CHINA

For accurate simulation studies on distribution of electromagnetic field induced by Tran-cranial Magnetic Stimulation, a real human head conductivity model with deep cerebral structure was reconstructed from MRI raw data, by using of MIMICS and ANSYS. This model reflects geometric structural information of Scalp, Skull, Cerebrospinal Fluid (CSF), Gray Matter, White Matter, Cerebellum, Ventricle and Eyeballs. The ventricular structure has relatively higher conductivity, whose effect on induced field could not be neglected. This paper mainly introduces the method to establish the ventricle part of the entire head model, which is used for ANSYS low-frequency magnetic simulation, while the way to generate other parts is similar and accomplished. On the platform offered here, study on specific individual subject would be easy and practicable. Deep structures will be produced vectorial in the future work.

SP101.7 - Study on electric field in real head model induced by H-coil

**Author(s):** Huanhuan Cheng, Chen Zhao, Zhipeng Liu, Tao Yin

Institute Of Biomedical Engineering, Chinese Academy of Medical Sciences, Tianjin/CHINA

To study the distribution of induced electric field in human brain under the H-coil and to explore the deep character of H-coil, this paper builds a real head model with limbic system inside, and an H-coil model close to the real head model. The electric field distribution in scalp and limbic system induced by H-coil was calculated via finite element method and the results were compared with those of figure-of-eight coil. It is found that the deep field performance of H-coil was much better than figure-of-eight coil. Although the induced electric field by H-coil is not focusing on scalp, it can concentrate deeply on anterior cingulate cortex, which is an important part of limbic system. It provides a valid evidence for H-coil to stimulate deep brain structures.
De-escalation of therapy will result in cure and toxicity rates which are different from the current standard-of-care. This balance between the two is explored implicitly by clinical trials which are explicitly examining de-escalation of therapy. The currently accepted equilibrium did not evolve through a quantifiable methodology, nor do the current trials address the issue of determining the optimal operating point.

Methods:
We developed an outcome model for oropharyngeal cancer which combines cure rates and late toxicity effects into a single quality of life metric. We chose an Influence Diagram to model the decision process because it can incorporate probabilities from previous clinical trials, retrospective analysis, and the beliefs of experienced physicians. We used a Markov model to calculate Quality-Adjusted Life Years (QALYs) for outcomes.

We performed sensitivity analysis to determine the robustness of the model predictions to model parameters, see Fig. 1. In particular, the sensitivity of individual patient preferences was explored in the event that a single standard-of-care approach cannot be taken for this disease site.

RESULTS AND DISCUSSION:
In order to change clinical practice the QALYs for de-escalated therapy must be higher than for standard therapy. We delineated the outcomes of the trials which would and those which would not change clinical practice, within the boundaries of our sensitivity analysis. This type of model has broad applicability to other disease sites in radiotherapy and to clinical trials in medicine in general. Developing the clinical decision model up front could help design a trial that can provide the necessary information for changes in clinical practice.

SP102.2 - Large-scale data of basic patient and treatment characteristics significantly improve predictions for post-radiotherapy dyspnea

Author(s): Timo M. Deist1, Arthur T.C. Jochems1, Cary Oberije1, Andre Dekker1, Katrien Vandecasteele1, Yolande Lievens2, Johan Van Soest1, Philippe Lambin2
1Department Of Radiation Oncology (maastro Clinic), GROW - School for Oncology and Developmental Biology, Maastricht University Medical Center, Maastricht/NETHERLANDS, 2Radiation Oncology Department, University Hospital Ghent, Ghent/BELGIUM, 3Department Of Radiation Oncology (maastro), Maastricht University Medical Centre+, Maastricht/NETHERLANDS

Purpose
Dyspnea is a known side effect of lung radiotherapy. Personalized medicine approaches require reliable models predicting the patient-specific risk. As the number of events is limited, large datasets are needed for model building and these can be obtained by using data from routine clinical practice. This approach limits data to basic patient and treatment features with an increased likelihood for incompleteness and errors. We show that such models for post-treatment dyspnea enhance predictions even if solely based on basic data from clinical practice.

Materials/Methods
Clinical data were collected retrospectively (2008-2014) from MAASTRO Clinic, the Netherlands, consisting of dyspnea levels before and after radiotherapy, chemotherapy type, and total tumor dose during therapy. 1031 lung cancer patients with a pre-treatment dyspnea score below 2 (according to CTCv.3 or 4) were selected to ensure non-iatrogenic dyspnea did not bias the results. A validation set of 82 patients was provided by Ghent University Hospital, Belgium. A Bayesian Network was learned to predict an increase in the dyspnea score given pre-treatment dyspnea, chemotherapy type, and total planned radiation dose. For comparison, another estimator was constructed solely based on pre-treatment dyspnea which is known to carry high predictive value.
SP102.3 - Substituting human MRI-observed tumor length with automated tumor length calculations for prediction model application

**Author(s):** Johan Van Soest¹, Jeroen Buijsen¹, Philippe Lambin¹, Vincenzo Valentini², Andre Dekker¹

¹Department Of Radiation Oncology (maastro), Maastricht University Medical Centre+, Maastricht/NETHERLANDS, ²Department Of Radiotherapy, Università Cattolica del Sacro Cuore, Rome/ITALY

**Introduction**

The development and use of prediction models in radiation oncology is emerging, especially in the context of individualized medicine. Although prediction models can indicate clinical outcomes, automated execution is a problem when information is only available as unstructured text (or missing). For example, van Stiphout et al. (PMID: 21176986) developed 3 prediction models to predict a pathologic complete response (pCR) in rectal cancer patients. In two out of three prediction models, tumor length (determined by radiologists on MRI scans) is used as a model variable, which needs to be manually extracted from free-text radiological reports. In this study, we attempted to find another measurement method for tumor size in already available data, and to measure its influence when applying it to the pre-treatment (clinical) pCR prediction model as a substitute for tumor length measured by a radiologist on MRI.

**Methods**

We used a dataset of 71 patients having a pre-treatment PET-CT scan and clinical radiotherapy gross tumor volume (cGTV) delineations available. For 41 of these patients the tumor length observed by a radiologist on an MRI was available. We used either this cGTV directly or a semi-automatic PET-threshold based GTV (tGTV) using 40% of the maximum of the standardized uptake value on the PET-CT scan. For both cGTV and tGTV, we calculated the volume, maximum Euclidian and axial distances (transversal perspective). Afterwards, we determined the correlation between MRI-observed tumor length and the computed metrics; using univariate regression analysis. Finally, we substituted the tumor length for the computed metrics in the clinical prediction model, and calculated the area under the receiver operating curve (AUC).

**Results**

Results of the correlation and substitution are shown in the table below. Based on this table, there is a significant correlation for the Z-axis, determined by a regression coefficient closest to 1 for both cGTV and tGTV. For the cGTV and tGTV, substituting the tumor length along the Z-axis resulted in a reasonable performance comparable to the original model (AUC 0.69 and 0.70), and resulted in a better performance for tGTV volume (AUC 0.78).

---

**Results**

The enhanced model and the estimation only using pre-treatment dyspnea have been cross-validated using 10 folds. The enhanced model outperforms the univariate estimation with an average AUC of 0.7319 versus 0.6852. The additional features yield a significantly different AUC (p-value<0.01, Wilcoxon signed-rank test). These findings are externally validated with the enhanced model increasing the AUC from 0.5740 to 0.6236.

**Conclusions**

Improvements in the prediction of worsened dyspnea after lung radiotherapy are achieved using only clinical patient and treatment data. This example provides additional evidence for the potential of prediction models based on clinical data to improve patient care and furthering the goal of personalized medicine.
Conclusion
We have shown a correlation between the MRI-based tumor length and GTV-based distances; specifically for the Euclidian, Z-axis distance and volume. In general, the semi-automatic IGTV dimensions are better for substitution of the MRI-observed tumor length. Although the results are promising, this dataset is too small (N=71; positive events: 14) to make final conclusions and requires an external validation.

SP102.5 - Design and implementation of an IT management system for a Medical Physics Department activity workflows.  
Author(s): Leonello Servoli1, Massimiliano Paolucci1, Bruno Cechucci1, Roberto Di Lorenzo2, Mariano Gattafori2, Mario Tiburzi2, Alessandro Carnevale2  
1Istituto Nazionale di Fisica Nucleare, Sezione Perugia/ITA-LY, 2BTREE Srl, Foligno/ITALY

The everyday activities of a Medical Physics Department, either in a single Hospital or in a network of Hospital and Medical Institutions, are very complex and the management of the data flow coming from the different tasks, of the scheduled quality controls and mainte-
widely used illumination correction methods in the segmentation stage. The first illumination correction technique was developed by making use of morphological operators, specifically the morphological closing. The second illumination correction technique was the algorithm known as Retinex. Performance measurements of the Mean Shift implementations were included with further comparisons of two existing segmentation techniques; image thresholding using Otsu’s method and Gradient Vector Flow (GVF) Snakes. The classification results of using two different classifiers are also demonstrated as part of the complete melanoma detection system. The first classifier was based on Support Vector Machines (SVMs). The second classifier used linear discriminant analysis with various discriminant functions: linear, quadratic and mahalanobis distances. This approach demonstrates enhanced classification capabilities of melanoma detection which can also be extended to other dermatologic applications.

SP102.7 - Fuzzy-state machine for Triage priority classifier in emergency room

**Author(s):** Agustín I. Cabrera Llanos1, María G. Ramírez-Soto-lo2, Emmanuel S. Sánchez Velarde2, Itxamñá O. Rico-Aseñención2, Nayely R. Budar-Alemán2, Alejandro A. Soto-De Ávila2, Rodrigo Sánchez-González2

1Bioprocesos, Unidad Profesional Interdisciplinaria de Biotecnología - IPN, Distrito Federal/MEXICO, 2Bioprocesos, Unidad Profesional Interdisciplinaria de Biotecnología, Distrito Federal/MEXICO

In this paper, a fuzzy classifier stage of a patient in the emergency room is presented. This classifier is divided into 3 stages: data entry by staff health, the evaluation provided by the software and finally the creation of a report for electronic patient file. A clinical classification system called triage give us the severity and priority of the patient, taking into consideration parameters like consciousness, blood pressure, appearance, temperature, heart rate and respiratory rate, achieving an effective pre valuation. The program is designed for adult patients aged 18 to 40 years.

SP102.8 - An Australian mining boom: development of an Australian radiotherapy datamining network for rapid learning from clinical data to support improved clinical decisions

**Author(s):** David Thwaites1, Lois Holloway2, Michael Bailey3, M Samir Barakat4, Martin Carolan4, Geoff Delaney5, Matthew Field1, Andrew Miller5, Johan Van Soest5, Shalini Vinod5, Sean Walsh1

1Institute Of Medical Physics, School Of Physics, University of Sydney, Camperdown, Sydney/AUSTRALIA, 2Department Of Radiation Oncology, Liverpool & Macarthur Cancer Therapy Centres and the Ingham Institute, Liverpool/NSW/AUSTRALIA, 3Medical Physics/medical Informatics, University of Wollongong, Wollongong/AUS- TRALIA, 4Radiation Oncology, Illawarra Cancer Care Centre, Wollon- gong/AUSTRALIA, 5Department Of Radiation Oncology (maastro), Maastricht University Medical Centre+, Maastricht/NETHER- LANDS, 6Department Of Radiation Oncology, Liverpool & Macarthur Cancer Therapy Centres, Liverpool/NSW/AUSTRALIA

**Objective:** Large amounts of data are routinely collected on radiotherapy patients, which can potentially provide additional clinical evidence to inform better clinical decisions. A collaborative project has begun between the MAASTRO clinic and a pilot network of Australian cancer centres, to validate and implement MAASTRO-developed prediction models (PMs) in Australian clinical practice and assess their impact on decisions for future patient treatment. Wider objectives include developing multi-institutional rapid learning, to enable PM evolution by incorporating more centres/data, using a distributed learning approach of transporting the model to the data, rather than data out of the centres, thereby protecting data privacy.

**Methods:** Two initial stand-alone pilots were conducted: one on datasets for radically-treated Stage I-IIIB non-small cell lung cancer (NSCLC) patients in the Liverpool Hospital Cancer Centre and the second on radically-treated Stage I-IV larynx patient datasets in the Illawarra Cancer Care Centre, both Pinnacle+Mosaiq users. Open-source rapid learning systems, using Semantic Web based tools, were installed, supporting collection of data, from the TPS and OIS databases, relating to the patients, diseases, treatments and recorded outcomes. The MAASTRO PMs were learned (on ‘training cohorts’) and validated against local datasets (‘clinical cohorts’). Further lung studies are currently underway in three other hospitals (Eclipse+Aria and Pinnacle+Mosaiq users).

**Results:** For the lung patients, of 419 datasets identified meeting the PM criteria, 159 had all required data to be eligible for inclusion in the clinical cohort. Some missing data were imputed using Bayesian methods, increasing eligible datasets to 225. The larynx data were relatively complete: 109/125 datasets identified had all data parameters recorded to be eligible for inclusion. For both pilots, the MAASTRO PMs successfully predicted better and worse prognosis groups, but showing some differences to the models, which reflect ed differences between the Dutch and Australian patient groups and practice. For example, the PM-predicted good prognosis lung group was differentiated from a combined medium/poor prognosis group (2-year overall survival, 69% vs. 27%, p<0.001) in the Australian data. Stage was less able to identify prognostic groups; most good prognosis patients in this clinical cohort having higher stage disease. For larynx, the proportion of clinical cohort patients in the predicted poor/medium/good prognosis groups were 47%/42%/11%, compared to the training cohort defined as 25%/50%/25%. Thus the larynx model could classify different clinical cohort prognosis groups, but the good prognosis group was smaller, as the clinical cohort was older and had more advanced cancers, nodal spread and non-glottic cancers than the training cohort.

**Conclusion:** The technical infrastructure and the basic MAAS TRO prediction models support the prognosis prediction of lung and larynx patients in Australian clinical cohorts, showing promise for support of future personalized treatment decisions, improved treatment quality and potential practice changes. The infrastructure is being extended: for an initial distributed learning pilot between multiple NSW centres; for expansion into more NSW centres, other states and linkage to trials databases; and for model parameters to include radiomics data. Data quality for routine patients is vital when creating a rapid learning infrastructure, to maximize the information’s potential.

SP103 - Health Technology Assessment and Cost Effective Technologies for Developing Countries and Usability and Human Factors Engineering for Medical Devices and System Design: Part 2

TRACK 16: CLINICAL ENGINEERING, CLINICAL PHYSICS, AND PATIENT SAFETY

SP103.1 - Novel Medical Device Procurement Tracking Approach
Author(s): Gleb Donin, Ilya Ivlev, Silvie Jeřábková, Jakub Vacek, Peter Kneppo
Department Of Biomedical Technology, Czech Technical University in Prague, Kladno/CZECH REPUBLIC

This paper presents approaches implemented in the medical device procurement tracking system in the Czech Republic. The System was created to enable the monitoring and assessment of procurement efficiency and to provide valid information to different stakeholders during future medical equipment purchases planning. Data collection process was proposed and implemented into practice. Several reports run on the grounds of a multi-criteria comparison based on comprehensive data model, which enable to analyse the procurement data and to formulate hypotheses relative to procurement efficiency. The multi-criteria approach is based on the valuation of the medical equipment procurements upon the set of criteria specified by the user, such as procurement terms and conditions, medical equipment price and technical specifications. The System developed allows users to compare purchase contracts with the purpose of identifying their weaknesses and planning future purchases.

SP103.2 - Influence of shifting patients with off-axis tumor for Tomotherapy
Author(s): Yingjie Xu, Jianrong Dai, Zhihui Hu, Peng Huang, Pan Ma, Kuo Men, Ke Zhang, Minghui Li, Dawei Jin, Wenting Ren
Department Of Radiation Oncology, Cancer Institute & Hospital, Chinese Academy of Medical Sciences, Beijing/CHINA

Objectives:
For tomotherapy, it’s common practice to set up a patient centrally no matter where a tumor is in his or her body. Here is to evaluate the influence of shifting the patient on plan quality and treatment time if the tumor is off the rotational axis of tomotherapy machine.

Methods:
15 patients with off-axis tumor were chosen for planning in tomo-therapy planning system (Accuray Inc.). The off-axis distance ranged from 2 to 12 cm. In one group of plans, all patients were shifted in the planning system to make the tumor center coincide to the machine’s rotation axis (HiArt) while in the other group, all patients were not shifted. Except center position, all planning settings such as pitch, field width, and modulated factor were the same for two groups. Conformal index, homogeneity index and mean dose of normal tissue were compared in these two groups. So did the treatment time and monitor units.

Results:
The CI, HI and DNTmean were 0.84±0.053, 1.06±0.023, and 12.37 (quartile range 5.78) for the first group of plans (the plans with patients shifted), and were 0.84±0.053, 1.07±0.027, and 12.4 (quartile range 5.91) for the second group, respectively. There was no significance. But the treatment time was shorter for the first group, and the difference became larger with off-axis distance. So did the MUs. When the distance was more than 6 cm, the treatment time saving was over 10%. These changes were mainly caused by the machine’s flattening filter free design.

Conclusion:
For patients with large off-axis tumor, treatment time and MUs can be reduced significantly if the patients are shifted so that the tumor center coincides to the machine’s rotational axis.

SP103.3 - Smart pump user interface evaluation
Author(s): Carlos A.B. Viviani1, Saide Calil2
1Deb, UNICAMP, Campinas/BRAZIL, 2Department Of Biomedical Engineering, Unicamp, Campinas/BRAZIL

There are at least 73 infusion pump manufacturers registered with the Food and Drugs Administration (FDA).

Many events reported by the FDA occurred due to usability problems of medical devices, which are often related to lack of consistency in the interface. This may induce the user to error and consequently the occurrence of problems during the device operation.

To minimize such events, it is required a careful evaluation of the interface device and also its standardization.

Infusion pumps are always present in ECRI's reports as one of the devices that have the highest probability of risk to the patient.

The objective of this study is to verify the interfaces consistency of four infusion pumps developed by leading manufacturer in world market.

The methodology is structured in two stages. The first stage referred to the development of an appropriate set of criteria for comparing the interfaces of the smart infusion pumps. In the second stage, it was applied the developed criteria to the interfaces using the four pumps as a practical study.

Evaluation results showed that there is no standardization for designing medical devices of the same type and category; in this case study the smart pumps. It also suggested that each manufacturer designs a device considering only aesthetic issues and does not maintain any consistency with other manufacturers and even with other models or different version devices.

This preliminary study provides us with evidence that this lack of consistency between the interfaces of these devices can lead to usability problems, and can lead untrained users to error. Additional studies are needed to further investigation and thereby demonstrate qualitatively results.
A software to manage the data from continuous monitoring has been implemented in paediatric intensive and cardiac critical care units of a large, tertiary hospital, in Canada, but in its current version has not been integrated in clinicians' work. In this study, we present two components of a proposed four-phase project which each approach the human-computer interface (HCI) from two directions. Established human factors methods will be employed: first, from the computer side using heuristics or “rules of thumb”, frequently used in software design, and second, from the human-user side, using cognitive task analysis. These two phases aim to inform an optimized interface design eventually used to study the impact of this cognitive task analysis. These two phases of a proposed four-phase project which each approach the human-computer interface (HCI) from two directions.

In this phase, the interface was assessed using 14 heuristics, developed by leading experts in interface design and modified for medical devices. Three evaluators assessed the same version of the software for issues and their heuristic violations and severity. The first assessment was performed by a “double-specialist” with novice-level knowledge of both the clinical work and human factors; the second was performed by two domain experts each from clinical nursing and human factors fields.

In total, 68 usability issues were found; 23 were found in the first assessment, 45 were found in the second assessment, and 18 found in both assessments. These were associated with over 200 violations to the heuristics generally, of severity 2 (minor usability problem) or 3 (major usability problem). The most common types of heuristic violations were visibility, match, memory and error.

Cognitive task analysis (CTA) is generally referred to as the set of methods used to identify the mental demands and cognitive skills needed to complete a task. Monitoring and decision-making in the technology intense environment of an ICU requires a high degree of staff expertise to carry out these cognitive tasks. A cognitive task analysis was used to understand how different clinicians in the ICU use the information at their disposal to make decisions regarding patient care. Physicians, nurses and respiratory therapists make decisions for a range of tasks required for continuous care. They obtain their information from disparate monitoring technologies and an understanding of their prioritized information sources is key to the design of software interfaces aimed at facilitating their access and integration of this information. We designed four simulated, paper-based, scenarios to aid the CTA.

By using tools from decades of knowledge of software interface design and from structured methods of understanding the work of clinicians, basic usability issues and tasks can be identified. Results from these two directions will inform the next phase of testing, a low-fidelity usability study, using true-to-work tasks and inherent software interface issues.

**SP103.5 - Analysis and experimentation of plantar foot segmentation from thermographic digital images for preventive diagnosis of diabetic foot**

**Author(s):** Carolina Rosado1, Alex E. Dávila2, Yahir Pandzic2, Luis Viechahuaman2, Marko Alpiste2, Luis Carrolina Rosado1, Alex E. Dávila2, Yahir Pandzic2, Luis Viechahuaman2, Marko Alpiste2, Luis Perú

1Faculty Of Electronic Engineering, Pontifical Catholic University of Peru, Lima/PERU, 2Pontifical Catholic University of Peru, Lima/PERU

Plantar foot surface temperature is an important feature in type II diabetes as it is an early sign of foot ulcer. We have reviewed the scientific and technical foundations for the use of digital thermography of the sole of the foot as a prevention procedure to avoid foot ulceration. This project has progressed in the implementation of a new segmentation algorithm to analyze plantar foot temperature and its assessment by qualitative judgment. We have processed thermographic images of the feet. To achieve this we first proceeded to capture images from two soles of feet -surrounded or not by a foam block- and then to segment them using two different methods each of which include the iterative closest point (icp) Method: 1) fuzzy clustering modeling (FCM) and 2) growing seeds. Images properly segmented were judged by three observers who have estimated the quality of the contour tracing. Medians and quartile deviations are calculated to estimate the segmentation's quality. As a result, the quality contour tracing was less suitable when there was not a foam block surrounding the sole of foot while imaging was performed. Likewise, the segmentation using FCM was less suitable than the segmentation by growing seeds. Overall, these results suggest the possibility of avoid using foam block by optimizing the software with growing seed method which increase the comfort of patients and asepsis inside hospitals.

1Departamento De Física, Universidade Federal de Sergipe, São Cristóvão/BRAZIL, 2Departamento De Física, Universidade Federal de Sergipe, Aracaju/BRAZIL, 3Instituto De Pesquisas Energéticas E Nucleares, Comissão Nacional de Energia Nuclear, São Paulo/BRAZIL, 4Division Of Cancer Epidemiology And Genetics, National Cancer Institute, Bethesda/UNITED STATES OF AMERICA

We developed exposure scenarios of pediatric interventional cardiology using a newborn hybrid phantom and the radiation transport code MCNPX. Six angiographic projections (AP, PA, LAO45, RAO45, LAO90 and RAO90) were simulated considering three X-ray energy spectra (60, 70 and 80 kVp), focus-skin distance (FSD) not less than 45 cm and a 7 x 7 cm² field size. Equivalent and effective doses were computed and normalized by kerma-area product (KAP) resulting the conversion coefficients HT/KAP and E/KAP. The results showed highest HT/KAP values in AP projection at 80 kVp. Increasing photon energy, average E/KAP values presented relative differences of 18% (60 to 70 kVp) and 15% (70 to 80 kVp). E/KAP values were compared with those published for mathematical newborn phantom. Results showed relative differences of 14% for AP projection (70 kVp) and 60% for lateral projections (60 kVp).

We showed the simulator’s capabilities by the introduction of a small calcium block into a coronary artery of the beating heart phantom. Its detectability was tested while changing the simulated heart rate variability. The calcium block was easily detectable in the reconstructed images when simulating acquisition during normal cardiac rhythm. When heart rate variability was increased to 10%, the coronary artery block was not detected in the reconstructed images.

SP104.2 - Computed tomography of a beating heart: High resolution simulator for the assessment of motion artifacts during CT scan of the heart

**Author(s):** Yair Zak*, Vadim Beniagouev*, Sarah Cohen*, Dov Malonek*

1Medical Engineering, Ruppin Academic Center, Emek Hefer/ISRAEL, 2Gico System, Philips Healthcare, Haifa/ISRAEL

Computed tomography of internal organs is an important diagnostic tool for the clinician in spite the use of ionizing radiation with the potential for causing harmful deterministic and stochastic effects to the patients. CT angiography, that allows detecting and evaluating coronary heart disease, is a technological challenge as the image acquisition process is done while the heart is moving resulting in information loss. Fast acquisition and precise synchronization to cardiac motion are common techniques to reduce information loss, but they fail when irregular cardiac rhythm is encountered.

We have developed a computerized CT simulator to investigate the effect of irregularities in cardiac cycle during CT scan on the obtained image quality. The CT simulator utilizes high resolution computer phantom mimicking realistic cardiac motion with anatomically realistic heart and associated vasculature. Normal cardiac motion is generated using XCAT/HADES phantom generator with anatomical resolution exceeding 0.25 mm. Irregular cardiac rhythm is controlled by a dedicated ECG simulator capable of generating normal and abnormal rhythms. The simulator allows simulation of prospective gating technique (“Step and shoot”). Various reconstruction algorithms have been incorporated in the simulator. Effects of geometry of the scanner, pixel size, gantry rotation speed and other physical parameters on image quality can be studied.

We showed the simulator’s capabilities by the introduction of a small calcium block into a coronary artery of the beating heart phantom.

We suggest that such computerized simulator have the potential be used in future development of CT techniques, to investigate the effects of anatomy and motion on acquisition protocols and to customize imaging protocols for individual patients based on their measured heart rate variability.

SP104.3 - Development of Dynamic Anthropomorphic Heart Phantom for Computed tomography

**Author(s):** Ali Ursani*, Murray Rice*, Shailaja Sajjia, Fatima Ursani*, Narinder Paul*

1Medical Engineering, University Health Network, Toronto/ON/CANADA, 2Department Of Medical Imaging, toronto general hospital, toronto/ON/CANADA, 3Medical Imaging, University Health Network, Toronto/CANADA

**Background:**

Currently available large detector CT scanners with high rotational speed and dual-source have demonstrated good diagnostic accuracy for coronary artery disease. However, the appearance of a coronary stenosis during computed topographic coronary angiography (CTCA) does not always equate the actual blockage in the arteries. This discrepancy is due to calcified plaque can cause bloom artifact or similarly measured density of non-calcified plaque is strongly affected by partial volume artifact from adjacent densities including luminal contrast. Higher or irregular cardiac motions has significant role in producing these artifacts, hence multiple scans are required with different gating techniques. These limitations can be addressed by improvement in image reconstruction algorithms and acquisition techniques.

**Method:**

This project presents development of a realistic dynamic anthropomorphic heart phantom (DHAP), which can mimic any heart rhythm of patient while waiting in the holding area. The dynamic heart phantom driven in real time from the patient’s ECG; then can be scanned in the CT to establish the best gating protocol suitable to current heart rhythms of the patient. Once the protocol is established the patient can be scanned only applying single gating technique; hence significant radiation dose can be reduced for these patients.

The phantom can also support research studies addressing the detection issues due to cardiac motion in space and time domains. Thus phantom can also serve as a useful tool in building new CTCA.
can be used to understand and validate the impact of tumour motion on hybrid PET/MRI.

The phantom’s main torso compartment has internal dimensions of 274.5mm long with an oval profile of 292mm by 240.5mm. The lung compartments have oval profiles with internal dimensions of 89mm by 125.5mm, by 274.5mm long. The spine compartment also has an oval profile with internal dimensions of 32.3mm by 23.6m, by 274.5mm long. The superior-end cap has two fill holes; one to fill the spine compartment and a larger one to fill the torso compartment. The inferior-end cap has two through holes to match the profiles of the lung compartments, which allow a spherical tumour compartment with a stem to be mounted to an MRI-compatible motion stage. This motion stage from Vital Biomedical Technologies can provide user-defined motion profiles to move the tumour (Figure 1A).

The 3.5cm diameter spherical tumour compartment was filled with saline and 17kBq/mL of F18 to mimic tumour uptake of FDG. The torso compartment was filled with saline and 4.27kBq/mL of F18 to mimic normal background uptake in a patient body. The motion stage was programmed to produce a repeating 4 second sinusoidal cycle of linear motion that was 2cm long in the superior/inferior direction. PET/MR images were acquired on a Siemens Biograph mMR via T1-VIBE sequence with simultaneous list-mode PET acquisition.

Figure 1B shows that the co-registration of the PET and MRI was achieved with no post-processing, despite the presence of motion. The PET/MR/CT-compatible Tumour Motion Phantom can be used to generate accurate images of known geometries and reproducibly simulate respiration motion or user-defined motion profiles of a tumour.

**Specifications:**

- **Fluid Pump** (piston type):
  - Capacity: 270 ml
  - HR: 50 to 125 BPM
  - Piston stroke (max) = 140 ml@120 bpm

- **Heart module** (Urethane rubber 30A/ 60HU@120kVp; wall thickness = 1cm):
  - Chambers: Two; LV & RV; 70ml each at relaxed state.
  - End-diastolic volume [EDV] = up to 130 ml (typical 120 ml)
  - End systolic volume [ ESV] = down to 40 ml (typical 50 ml)
  - Arterial angular displacement around the axis = up to 2 cm

- **Software:**
  - NI LabVIEW Control Design and Simulation Module running on PC with the help of Quanser Q2-USB H.I.L control board. A pressure wave corresponding to the heart chamber movements is simulated and fed into the closed-loop PI position controller to drive the linear shaft of piston-pump.

**Results:**

Attached figure: Two trans-axial 0.5mm computed tomography images through the basal left ventricle (top right) and apical left ventricle (bottom right) show the presence of non-calcified plaque causing eccentric (top) and central (bottom) luminal stenosis.

Currently following studies are being carried out with the help of DAHP at UHN.

Study.1 - Optimal image reconstruction for detection and characterization of mixed coronary plaque during CTCA.

Study.2 - Influence of X-ray pulse duration on lung nodule sharpness during digital radiography in a dynamic anthropomorphic chest phantom.

**SP104.4 - Development of a PET/MR/CT Compatible Tumour Motion Phantom**

**Author(s):** John C. Patrick¹, Mohammad A. Tavallaei², Frank S. Prato³, R T. Thompson⁴, Maria Drangova⁵, Stewart Gaede⁵

¹Physics And Engineering, London Regional Cancer Program, London/CANADA, ²Imaging Research Laboratories, Robarts Research Institute, London/ON/CANADA, ³Medical Biophysics, Western University Canada, London/ON/CANADA

The development of PET/CT scanners has improved staging for lung cancer, especially for nodal and distant metastatic sites. In the case of chest wall infiltration and mediastinal tumours, MRI is superior to PET/CT. PET and CT are acquired sequentially and thus motion in PET that is acquired over minutes cannot be corrected with the CT, which is acquired over several seconds. Siemens’ hybrid PET/MRI acquires both modalities simultaneously, eliminating the impact of respiratory motion due to sequential scanning. This could have a major impact on respiratory-gated lung cancer radiotherapy. Before implementing PET/MRI for lung cancer radiotherapy clinically, the benefits of this novel imaging technique should be validated in an appropriate phantom. Therefore, the goal of this work is to demonstrate a PET/MR/CT compatible respiratory motion phantom that

SP105 - MRI: Novel Approaches and Molecular Imaging & Applications

TRACK 01: IMAGING

SP105.1 - Advancing MRI for Non-invasive Physiological and Cellular Imaging
Author(s): Hai-Ling Margaret Cheng
Institute Of Biomaterials & Biomedical Engineering, University of Toronto, Toronto/ON/CANADA

Magnetic resonance imaging (MRI) is a non-invasive, high-resolution whole-body imaging modality for probing deep tissue structures without requiring exposure to ionizing radiation. The exquisite soft-tissue contrast MRI affords is unparalleled, thus firmly establishing its importance in clinical diagnostic imaging. MRI also has great potential for imaging events at the physiological, cellular, and molecular level. Although most of these efforts currently remain within the domain of pre-clinical research, advancing MRI beyond conventional anatomical imaging is key to opening new avenues for exploration.

In this talk, I will describe the efforts in our laboratory to advance MRI for physiological, cellular, and molecular imaging for eventual translation to humans. Our emphasis is on “quantitation”, meaning that we use imaging to “measure” biological events. This focus is critical to improving the way we detect disease, since early changes in cells and tissue function often occur long before physical abnormalities become apparent, and having the ability to detect and measure these changes is crucial to early diagnosis and intervention. It will also enable us to tackle emerging applications, such as tissue engineering, where the ability to track transplanted cells and determine their fate or to monitor tissue development in vivo, can be assessed realistically only inside a living subject. The technical capabilities we are developing will be described alongside their application to guiding tissue-engineering approaches for regeneration and to new concepts for cancer detection (Figure 1) and cardiovascular imaging (Figure 2).

SP105.2 - Detection of Regional Radiation-Induced Lung Injury using Hyperpolarized 129Xe Localized Magnetic Resonance Spectroscopy
Author(s): Brandon Zanette1, Ozkan Doganay2, Elaine Hegarty3, Giles E. Santyr4
1Physiology And Experimental Medicine, The Hospital for Sick Children, Toronto/ON/CANADA, 2Department Of Medical Biophysics, University of Western Ontario, London/ON/CANADA, 3Robarts Research Institute, London/ON/CANADA, 4Department Of Medical Biophysics, University of Toronto, Toronto/ON/CANADA

Introduction: Radiation induced lung injury (RILI) remains one of the most important limitations of radiotherapy of the thorax. Magnetic Resonance Spectroscopy (MRS) using hyperpolarized 129Xe may be useful for early detection of RILI by quantification of gas exchange between lung air spaces, lung tissue (T), and red blood cells (RBC)1. Previous work using whole lung irradiation and 129Xe MRS has shown detection of inflammatory changes associated with RILI (i.e. pneumonitis) as early as two weeks post-irradiation in rats2. This work extends these methods to regional detection of RILI using localized MRS in a rat model involving irradiation of the right versus left lung.

Methods: Sprague Dawley rats were used following Western AUC-approved protocols. One cohort was irradiated with 18 Gy to the right thorax and incubated for two weeks, while the other cohort served as unirradiated controls. Localized 129Xe spectra were obtained from an 8x8 matrix in the coronal plane and processed to yield total tissue signal (ST) and total RBC signal (SRBC) for the whole lung as well as each of the left and right lungs, similar to Thind et al.3 For each rat, whole lung and individual lung (right and left) SRBC/ST ratios were calculated, after which ratios of SRBC/ST between right and left lungs (R/L) were calculated. Afterwards, lungs were removed, fixed, sectioned and stained (H&E) for histology.

Results: Eight rats were analyzed (three irradiated, five unirradiated). R/L was significantly different between the two cohorts (p = 0.009) with mean values 0.91 (± 0.08) and 0.69 (± 0.07) for the unirradiated and irradiated cohorts respectively. The difference between SRBC/ST between the cohorts was less significant for the left lung (p = 0.056) compared to the right (p = 0.019), while whole lung comparison was intermediate (p = 0.022).

Discussion: These results confirm that regional RILI differences are detectable at two weeks using hyperpolarized 129Xe localized MRS of rat lungs following single-lung irradiation of 18 Gy. The strong
Results and Conclusions: Similar to results given by Heikal et al., Fig. 1(g) shows that the spatial frequency response for the CS implementations was markedly lower than the fully sampled acquisition that they are intended to imitate (black plot). CMaCS (blue plot) provided a near two-fold increase in spatial frequency response compared to standard CS. However, due to potential B0 field variations across the FOV, a zero-order phase correction may prove insufficient for robust CMaCS, requiring more complex phase-handling.

SP105.4 - Gadolinium Labeled Glycosylated Nanomagnetic Particles as Metabolic Contrast Agents in Molecular Magnetic Resonance Imaging

Author(s): Sara --, Nader Riyahi-Alam, Soheila Haghgoo, Mehdi Khobi, Banafshe Nikfar, Ensieh Gorji, Behrouz Raffei

Tehran university of Medical Science, tehran/IRAN

Difficulties in the use, preparation, and cost of radioactively-labeled glycosylated compounds led us to this research and development study of a new gadolinium-labeled glucose compounds that do not
have a radioactive half-life or difficulties in its synthesis and utilization. Despite its good resolution, Magnetic Resonance Imaging (MRI) has low sensitivity, therefore, using MRI contrast agents, such as GD-DTPA (Magnevist) will improve tissue discrimination in MRI images.

The purpose of this study is the synthesis and physicochemical characterization of glycosylated gadolinium as metabolic contrast agent for molecular MRI (mMRI), in-vitro T1 relaxivity measurement and signal intensity of the glycosylated compounds has been also performed in comparison with magne-vist (GD-DTPA). Based on the structure of the 2-fluoro-2-deoxy-D-glucose molecule (FDG), first compound consisting of D-glucose conjugated with diethyleneglycol via N,N-carbonimidamide (CDI) mediated reaction, to achieve GD-DEG-DG, and characterized by various analytical technique, utilizes dynamic light scattering (DLS) to determine the size distribution. The nanoparticle size and morphology were using high resolution transmission electron microscopy (HTEM). In our study, the Gd-DTPA-DG were well defined nanoparticle with size 40 nm in diameter TEM images. While Gd-DEG-DG were 10 nm. The mean hydrodynamic diameter of nanoparticles, as measured by DLS, were 300 nm and 70 nm for GD-DTPA-DG and GD-DEG-DG, respectively. The synthesized GD-DTPA-DG and GD-DEG-DG were shown higher relaxometry rates in vitro relative to magne-vist. GD-DEG-DG and GD-DTPA-DG demonstrated shorter T1 than GD-DTPA at the same concentration.

This study shows that MRI of hyperpolarized $^{129}$Xe in the gas space and in the lung tissue is feasible, and can be used to detect increases in tissue signal in the lungs of irradiated rats as early as two weeks post-irradiation. An increase of approximately 50% in tissue signal was observed in the right lungs of the irradiated cohort compared to the unirradiated cohort corresponding to increases in tissue area (ie, pneumonitis) measured using histology. These methods should be readily translatable to human subjects given the growing availability of hyperpolarized gas technology in the clinic. Early detection of pneumonitis may allow adjustment to the radiotherapy plan and/or the application of alternate therapies to mitigate RILI.

SP105.5 - Hyperpolarized $^{129}$Xe Magnetic Resonance Imaging of a Rat Model of Radiation-Induced Lung Injury Involving Single-Lung Radiation Therapy

**Author(s):** Ozkan Doganay1, Elaine Hegarty2, Rolf F. Schulte3, Charles McKenzie4, Giles E. Santyr1
1Medical Biophysics, Western University, London/CANADA, 2The Hospital for Sick Children, Toronto/ON/CANADA, 3GE Global Research, Munich/GERMANY, 4Robarts Research Institute, London/ON/CANADA

Radiation therapy is a common treatment for lung cancer, but is limited by radiation-induced lung injury (RILI)[1]. It has been previously shown that Magnetic Resonance Imaging (MRI) with hyperpolarized $^{129}$Xe can detect changes in both lung tissue signal as well as exchange between gas and tissue (ie, pneumonitis) as early as two weeks following whole thorax irradiation in rats[2]. In this study, a novel MRI approach is developed for imaging of hyperpolarized $^{129}$Xe both in the gas phase and dissolved in lung tissue. The method is applied to a rat model of RILI involving single-lung irradiation.

The right thorax of three Sprague Dawley rats were irradiated with a cobalt-60 irradiator (18Gy), following previously described methods[2]. Three rats served as non-irradiated controls. 2D coronal spiral IDEAL[3] images were acquired using a repetition time (TR) of 300ms. Following three wash-in breaths of hyperpolarized $^{129}$Xe, IDEAL gas images and tissue images were acquired from the lungs within a breath-hold time of 6 seconds. Signal-to-noise ratios (SNR) of the averaged IDEAL gas images and the lung tissue images, for both the left lung (SGL, STL) and the right lung (SGR, STR) of both cohorts were calculated. To account for potential differences in ventilation and polarization, the lung tissue SNR values were normalized by respective gas SNR values for both left and right lungs (STL/SGL and STR/SGR). Following imaging, lungs were removed for histological examination.

Fig.1 shows coronal IDEAL gas (a) and tissue (b) images from a representative non-irradiated rat. STL/SGL and STR/SGR was strongly correlated with tissue area measured by histology (R=0.75), with a Pearson coefficient P-value=0.005 at p<0.01.

SP105.6 - Ultra-short Echo Time (UTE) Magnetic Resonance Imaging of Cortical Bone: An Undersampled Acquisition Study

**Author(s):** Yanchun Zhu1, Qun He1, Jiang Du2, Yaoqin Xie1
1Institute of Biomedical and Health Engineering, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen/CHINA, 2Department Of Radiology, University of California, San Diego/UNITED STATES OF AMERICA

Purpose: Ultra-short echo time (UTE) sequences have shown great utility in visualizing short T2 tissues like cortical bone which shows little or no signal with conventional clinical magnetic resonance imaging (MRI) techniques. Several short T2 contrast mechanisms have been developed to enhance bone contrast by suppressing signals from surrounding long T2 tissues including muscle and fat. These contrast mechanisms may significantly prolong the acquisition times.

**Methods:** A series of UTE pulse sequences were implemented on a 3-T Signa TwinSpeed scanner (GE Healthcare Technologies, Milwaukee, WI, USA) with a maximum gradient performance of 40 mT/m and slew rate of 150 mT/m/ms. In this paper, UTE, dual echo UTE (dUTE), adiabatic inversion recovery prepared UTE (IR-UTE) and adiabatic inversion recovery prepared dual echo UTE (IR-dUTE) with different undersampling acquisition ratios were compared by measuring signal-to-noise ratios (SNRs), contrast-to-noise ratios (CNRs), signal distortion, contrast, image sharpness and streak artifact power. The feasibility of using undersampling acquisition in UTE approaches was demonstrated by imaging cortical bone in vitro and in vivo using the clinical 3T scanner.

**Results:** Results showed that UTE, dUTE, IR-UTE and IR-dUTE data acquisitions can be highly undersampled to save scan time, while providing images with limited undersampling artifact especially for IR-UTE and IR-dUTE acquisitions. Figure 1 shows the dUTE
Abstracts

imaging that can provide the Fractional Anisotropy (FA) index which evaluates many parameters that could be used as biomarkers to find biomarkers that help us in the diagnosis of this disease and in improving its medical treatment.

Among the MRI advanced techniques are: a) The diffusion tensor imaging that can provide the Fractional Anisotropy (FA) index which takes values between 0 and 1 and it is used to evaluate the integrity of the white matter; b) The Voxel-wise morphometry that helps to quantify the volume and the amount of gray and white matter in the brain; c) The functional Magnetic Resonance Imaging (fMRI) based on the Blood Oxygen Level Dependent (BOLD), that is used to identify different brain areas that are activated during specific tasks and to infer the connectivity between different brain regions that may be interconnected, as it is shown in the resting state connectivity.

Methods:

A total of 16 voluntary subjects participated in this study, 8 patients with ALS (age 18-54) and 8 control subjects, age matched, without antecedents of neurologic or psychiatric disease. The images were acquired with a Philips magnetic resonance scanner, Ingenia 3.0 T with a 32 channel head coil. We acquired sagittal T13D-weighted images with spatial resolution of 1x1x1mm³, axial diffusion tensor images with 33 independent directions of diffusion and b of 1000 s /mm². Axial fMRI based on BOLD with echo planar images (EPI) technique, TR=2s and 150 dynamics. Axial T2FLAIR-weighted images were also acquired to identify intra cortical and supra cortical lesions. The software FSL v.2.0 was used for the analysis of the data.

Results:

The FA is decreased in the corticospinal tract in bilateral form and in the posterior limb of the internal capsule. The Voxel-wise Morphometry analysis shows a decrement of the volume of all the brain in patients with ALS. The motor network obtained by the resting state

Conclusion: This study has shown that UTE imaging of cortical bone with highly undersampling acquisition (acceleration factor up to 23) is feasible when surrounding long T2 tissues are efficiently suppressed.

Figure 1: dUTE undersampling study of in-vivo distal tibia. dUTE undersampling images of distal tibia.

The purpose of this study was to discriminate the brain activation patterns associated with the anxiety-provoking distracter during the working memory (WM) maintenance for the human faces between patients with obsessive compulsive disorder (OCD) and healthy controls by using a function magnetic resonance imaging (fMRI).

Twelve patients with OCD (mean age = 31.3±7.4 years) and 12 healthy controls (mean age = 33.3±7.8 years) underwent the functional MRI on a 3.0 Tesla MR Scanner (Siemens Medical Solutions, Germany). The activation paradigm consisted of a string of “encoding - WM maintenance - distracter - retrieval.” In the encoding task, three different human faces sequentially appeared once on a quarter coordinate of a screen monitor. During the delay time following the encoding, the subjects were asked to maintain the WM for the encoded faces. Then, distracters were given to the subjects while maintaining the WM of the encoding step, in which the distracters consisted of an anxiety-provoking picture and a neutral picture. In the retrieval task, either of the face presented in the encoding task or a new face was presented. The brain activation mapping and the resulting qualification were processed by SPM8.

The average scores of perceived anxious emotion for anxiety-provoking picture were 7.8±1.4 and 7.2±1.4 in patients with OCD and healthy controls, respectively. The scores for the face recognition task with anxiety-provoking distracters were 67.8±9.1% and 68.3±11.9% in patients and healthy controls, respectively, while the scores for neutral distracters were 62.1±15.7% and 70.0±12.1%, respectively. The patients with OCD showed significantly decreased activities in the ventrolateral prefrontal cortex, superior parietal gyrus, middle temporal gyrus, and fusiform gyrus during the WM maintenance with the anxiety-provoking distracters as contrast to healthy controls, whereas the patients with OCD significantly increased activities in the inferior temporal gyrus and median cingulate gyrus (p<0.001).

It is concluded that our findings provide an evidence for the differential brain activation patterns associated with anxiety-provoking distracter between patients with OCD and healthy controls during the delay interval of the WM task. This finding will be helpful to understand the neural mechanism related to general impairment of emotional function in patient with OCD.

SP105.8 - Fractional Anisotropy, Voxel Wise Morphometry and Resting State in Patients with Lateral Amyotrophic Sclerosis

Author(s): Maria M. Lopez-Tita, Salvador Garcia, Lourdes M. Martinez

Imágenes Cerebrales, Instituto Nacional de Psiquiatría, México/MEXICO

Introduction:

The Amyotrophic Lateral Sclerosis (ALS) is a degenerative disease that is characterized by the damage of the Upper Motor Neurons (UMN) and the Lower Motor Neurons (LMN). Many studies have found that motor areas are affected by this disease, being the main affected areas the corticospinal tract, the posterior limb of the internal capsule and the anterior and medial parts of the corpus collosum; other studies have also found a general decrement of the gray matter in all the brain. The ALS has a difficult prognosis because the symptoms can be misleading; therefore it is really important to find biomarkers that help us in the diagnosis of this disease and in improving its medical treatment.

The Magnetic Resonance Imaging (MRI) is a non invasive neuroimaging method that offers information in vivo of the brain structures. This method counts with different advanced techniques which evaluates many parameters that could be used as biomarkers to identify distinct diseases or disorders.
SP106.1 - Proton therapy – close to becoming mainstream
Author(s): Thomas Bortfeld
Massachusetts General Hospital and Harvard Medical School, Boston/UNITED STATES OF AMERICA

The number of patients treated with proton therapy is now well over 100,000. The field of proton therapy is growing at a remarkable and stable growth rate: the numbers double every ten years. To make this growth rate sustainable, and for proton therapy to become mainstream, we argue that two goals must be achieved: First, proton therapy must become cheaper and more compact. Secondly, we must be able to fully exploit the physical potential of proton therapy.

Many developments are underway to help with the first goal. Single room solutions and “compact” proton machines are becoming increasingly available. We will give an overview of the available options and report on our own experience with proton therapy retrofitted in a conventional treatment area. The biggest proton therapy component and one of the most expensive ones is the gantry. Based on an analysis of almost 5,000 patients treated with gantries in our center, we find that the vast majority of them could have been treated without the gantry. Developments of robotic patient positioning and immobilization, advanced in-room imaging solutions, as well as advances in pencil beam scanning delivery, will further reduce the need for a gantry.

The second goal requires the precise localization of the end of range of the proton beam in the patient. There are a number of developments underway to reduce range uncertainties. We will report on advances of measuring the proton range through the prompt gamma radiation produced by the proton beam in the patient. This will allow one to determine the proton range with millimeter precision in realtime.

SP106.2 - Monte Carlo-based Inverse Treatment Plan Optimization for Intensity Modulated Proton Therapy
Author(s): Yongbao Li¹, Zhen Tian², Ting Song², Zhaoxia Wu¹, Yaqiang Liu¹, Steve B. Jiang², Xun Jia²
¹Department Of Engineering Physics, Tsinghua University, Beijing/CHINA, ²Department Of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas/UNITED STATES OF AMERICA

Intensity-modulated proton therapy (IMPT) can achieve a better dose distribution than passive scattering or uniform scanning. For IMPT optimization, Monte Carlo (MC) is desired for spots dose calculations because of the high accuracy in heterogeneous cases. Due to its capability of computing linear energy transfer (LET), MC-based IMPT planning is preferred in biological optimization scheme. However, MC simulation is too slow to be used for this purpose. Although GPU-based MC engine has been developed, the achieved efficiency is still not ideal. The purpose of this work is to develop a new scheme to include GPU-based MC into IMPT. The conventional approach for this purpose is simply using MC repeatedly for each spot dose calculations. However, this is not the optimal approach, because of the unnecessary computations on spots that turned out to have very small weights after IMPT optimization. Memory writing conflict also poses a challenge, if one sequentially compute dose at each spot. To solve these problems, we have developed a new MC-based IMPT plan optimization framework that iteratively
performs MC dose calculations and plan optimization. At each dose calculation step, the particles are sampled from different spots based on previously optimized spots intensity map with Metropolis sampling method. Simultaneous handling multiple spots also solves the memory writing conflict problem. We validated the proposed MC-based optimization schemes in one prostate case. It took 5-6 min of total computation time including both spots dose calculation and optimization with only one GPU card for the proposed method, whereas a conventional method naively using MC for spot dose calculations would be ~2-3 times slower.

**SP106.3 - FoCa: a protontherapy treatment planning system written in object-oriented MATLAB**

**Author(s):** Daniel Sanchez-Parcerisa, Alejandro Carabe

**Radiation Oncology, Hospital of the University of Pennsylvania, Philadelphia/UNITED STATES OF AMERICA**

**Purpose:** Monte Carlo transport codes are useful in protontherapy research as they provide accurate calculations, but at the cost of long calculation times. On the other hand, commercial treatment planning systems provide fast dose calculation but with limited access to the calculation engine behind them. To address these issues, we developed FoCa, an in-house treatment planning system, developed entirely in object-oriented MATLAB, which includes forward dose and LET calculation of proton radiotherapy plans in both active and passive modalities as well as a generic optimization suite for inverse treatment planning. **Methods:** Our approach was to provide the user with a set of classes dealing with the different aspects of a treatment planning system (CT importing, structure sets, dose kernel calculation, et cetera). We chose MATLAB for its fast prototyping capabilities, its speed at matrix calculations and its extensive geometry libraries. FoCa implements the proton-convolution-superposition algorithm for dose calculation and a similar pencil beam algorithm for analytical LET calculation. We included a user-friendly GUI for basic user interaction, as well as scripting capabilities for advanced operations. The inverse treatment planning framework is presented with an open architecture, not specific to any treatment mode or optimization algorithm, which allows researchers to work on their own optimization methods or therapy modalities. **Results:** We developed and tested the FoCa code. The validation results show a good agreement with the commissioning data, the 3D dose distributions based on patient-specific CT data calculated by a commercial treatment planning system, and 3D Monte Carlo calculations of dose and LET performed with Geant4. Finally, the inverse treatment planning suite was used to produce the first prototype of intensity-modulated, passive-scattered proton therapy, using 13 passive scattering proton fields and multi-leaf modulation to produce a concave dose distribution on a cylindrical solid water phantom without any field-specific compensator. **Conclusions:** We have demonstrated the validity and capabilities of the FoCa TPS in a wide range of setups. Its current and potential uses range from the fast calculation of any physical, radiobiological or clinical quantity in a patient CT geometry, to the development of new treatment modalities not yet available in commercial treatment planning systems. FoCa is currently available within our institution to a selected number of test users and it will be made available to the research community after all the necessary testing has been completed.

**SP106.4 - Assessment of the limitations of the dose calculation algorithm of a commercially-available treatment planning system for proton pencil beam scanning**

**Author(s):** Jessica E. Scholey, Liyong Lin, Christopher G. Ainsley

**Department Of Radiation Oncology, The University of Pennsylvania, Philadelphia/PA/UNITED STATES OF AMERICA**

This study evaluates the accuracy and limitations of a commercially-available treatment planning system's (TPS) dose calculation algorithm for proton pencil-beam scanning (PBS) and quantifies the sensitivity of the accuracy to the proton beam source modeling. In-air fluence profiles of PBS spots were modeled in the TPS alternately as single- (SG) and double-Gaussian (DG) functions, based on fits to commissioning data. Uniform-fluence, single-energy-layer square fields of various sizes and energies were calculated with both beam models and delivered to water. Dose was measured at several depths (Figure 1). For lower energies (100-150 MeV), the DG model fits the measurements well at all depths, while the SG model does not. For higher energies (150-225 MeV), both the SG and DG models fit the measurements well at shallow depths (< 4 cm), but not deeper, where dose contributions from proton-nuclear interactions become important, suggesting a limitation of the algorithm. The possibility of using, instead, a third model, based on double-Gaussian functions with parameters contrived to offset this inadequacy (DGC) was therefore investigated.

Eleven cuboid-dose-distribution-shaped fields with varying range/ modulation and field size were subsequently generated in the TPS, using each of the three beam models described, and delivered to water. Dose was measured at the middle of the spread-out Bragg peak. Percent differences between calculated and measured doses (Table 1) were greatest for the SG model, increasing the smaller the field. The DG model showed improvements for all field sizes in shorter range beams, though the percent differences for smaller fields persisted in longer range beams. The DGC model was, however, able to predict the measurements to within 2% for all beams.

It can be concluded that while neither SG nor DG models, employed as intended, are ideally suited for routine clinical use, the TPS's DG model can be tuned judiciously to yield acceptable results.
SP106.5 - Impact of the microdosimetric spread on cell survival data analysis

Author(s): Gloria Bäckström¹, Fernanda Villegas-Navarro², Shirin A. Enger¹, Anders Ahnesjö²
¹McGill University, Montreal/CANADA, ²Uppsala University, Uppsala/SWEDEN

Purpose/Objective

The microscopic uncertainty of the energy imparted (microdosimetric spread, MDS) at the cellular/cell nuclei level due to the stochastic nature of ionizing radiation is normally not explicitly considered during parameterization of experimental survival fraction data. The magnitude of the MDS is higher for protons than for photons because of the known differences in track structures. The aim of this work is to present a method to quantify the impact of MDS on the biological radiation response. We estimate the effect on the α and β parameters of the linear quadratic (LQ) model used to describe experimentally obtained cell survival curves in different volumes sizes for various radiation qualities.

Materials and Methods

The Monte Carlo transport code LionTrack was used to simulate event-by-event proton tracks in liquid water for the energies 0.91, 1.4, 1.72, 3.18, 3.59, and 4.97 MeV/u, as well as for a 60Co source. The frequency distribution of specific energy for one track f(z,D) and the dose dependent frequency distribution of specific energy f (z,D) were calculated with in-house analysis codes for a range of spherical volume sizes typical of cell nuclei. Experimentally obtained survival curves intrinsically account for the MDS. When the specific energy z given by f (z,D) is weighted with the LQ equation, \( \alpha + \beta z^2 \), the α and β values based on D instead of z exclude the MDS variations and can be determined by fitting α and β to survival curves calculated from published αexp and βexp values. The RBE10 at 10% survival with 60Co as the reference radiation for the αexp and βexp was also factorized into a factor equal to the RBE for the fitted α and β values (RBEinh), and a factor representing effects of the MDS (RBEMDS), RBEMDS for a tissue with variable cell nuclei sizes was calculated by weighting f (z,D) with the size distributions presented by Poole et al [Submitted to Med. Phys. 2015] for healthy and tumor tissues.

Results

The f(z,D) can be quite well represented by a narrow normal distribution for the lowest LET radiation (60Co) even at small volumes, becoming wider and skewed towards lower specific energies with increasing particle LET. The relative MDS increases with decreasing dose and decreasing volume. The RBEMDS factor decreases with increase in LET and volume thereby reducing the RBEinh. For a heterogeneous size sample, the RBEMDS for healthy tissue reduces the RBEinh the most when compared to the tumor tissue.

Conclusions

Our data suggests that the MDS in experimental data smears out the higher efficiency of the inherent RBE. The MDS component in a clinical scenario with an irradiated volume that consists of cells with different sizes might be smaller for tumor tissues than for healthy tissues due to the higher number of larger nucleus sizes in tumor tissues.

SP106.6 - Magnetically scanned-beam proton radiography using Micromegas detectors

Author(s): Derek Dolney¹, Godwin Mayers², Mitch Newcomer², Douglas Bollinger¹, Niral Desai², Robert Lustig¹, Kevin Teo¹, Richard Maughan¹, Timothy D. Solberg¹, Robert Hollebeek²
¹Radiation Oncology, University of Pennsylvania, Philadelphia/PA/UNITED STATES OF AMERICA, ²Physics And Astronomy, University of Pennsylvania, Philadelphia/PA/UNITED STATES OF AMERICA

Purpose: While the energy of therapeutic proton beams can be adjusted to penetrate to any given depth in water, range uncertainties arise in patients due in part to imprecise knowledge of the stopping power of protons in human tissues. Proton radiography is one approach to reduce the beam range uncertainty, thereby allowing for a reduction in treatment margins and dose escalation.

Methods: The authors have adapted a novel detector technology based on Micromes Gaseous Structure ("Micromegas") for proton therapy beams and have demonstrated fine spatial and time resolution of magnetically scanned proton pencil beams, as well as wide dynamic range for dosimetry. In this work, proton radiographs were obtained using Micromegas 2D planes positioned downstream of solid water assemblies. The position-sensitive monitor chambers in the IBA proton delivery nozzle provide the beam entrance position.

Results: Radiography with Micromegas detectors and actively scanned beams provide spatial resolution of up to 300 μm and water-equivalent thickness (WET) resolution as good as 0.02% (60 μm out of 31 cm total thickness). Dose delivered to the patient by the proton radiography technique would be 2 cGy. The spatial resolution as a function of sample rate and number of delivered protons is found to be near the theoretical Cramer-Rao lower bound. Using the CR bound, we argue that the imaging dose could be further lowered to 1 mGy, and still achieve sub-mm spatial resolution, by relatively simple instrumentation and beam delivery modifications.

Conclusion: For proton radiography, high spatial and WET resolution can be achieved, with minimal additional dose to patient, by using magnetically scanned proton pencil beams and Micromegas detectors.
SP107 - Beam Delivery

SP107.1 - A Quantitative Analysis of Teletherapy in Low Resource Settings: Cobalt or Linac?

**Author(s):** Rachel Mccarroll1, Bassem Youssef1, Beth Beadle1, Maureen Bojador2, Rex Cardan3, David Followill1, Anuja Jhingran1, Christoph Trauernicht4, Peter Balter1, Laurence Court1

1University of Texas MD Anderson Cancer Center, Houston/UNITED STATES OF AMERICA, 2University of St. Tomas Hospital, Manila/PHILIPPINES, 3University of Alabama Birmingham, Birmingham/UNITED STATES OF AMERICA, 4Groote Schuur Hospital and University of Cape Town, Cape Town/SOUTH AFRICA

**Purpose:** There exists a deficit of more than 6,500 megavoltage teletherapy units worldwide, many in low resource-settings. Medical linear accelerators and cobalt units would address this need, and the tradeoffs between them have been compared qualitatively in the literature. Often discussed are dose rate, power infrastructure, and machine downtime all of which affect machine availability and treatment time. We have quantitatively addressed these topics and their effect on patient throughput (treatments/day).

**Methods:** Patient treatment time was calculated as the sum of patient set-up, beam-on, and mechanical motion time, with input data from clinical observation and electronic records (1000+ patients). The following treatment techniques were considered: linacs (conformal with MLC, Step-and-Shoot IMRT, Dynamic IMRT, and VMAT), and cobalt units (conformal therapy with and without MLC). Power data from The World Bank for 44 African countries were divided into three power scenarios based on frequency of outages. We assumed that cobalt units remain operable during outages using a backup generator. Machine downtime data was acquired from in-house records (linacs) or experienced users (cobalt).

**Results:** Low dose rates associated with cobalt units increase conformal treatment beam-on time between 0.6 and 2 minutes, depending on source activity. This represents between 14% and 28% of the total treatment time. Advanced modalities increase treatment time, particularly step-and-shoot IMRT which requires the most mechanical motion time, an average of 2.6 minutes (28% of total treatment time). VMAT and Dynamic IMRT treatments have shorter mechanical motion time (0.5 and 1 minutes, respectively) but longer beam on time (2 and 1.9 minutes, respectively). Patient throughput, under each of the seven treatment techniques and three outage scenarios, is shown below. In scenarios of “fewer” or “few-est” outages, the two machines are comparable when linac delivers conformal or VMAT treatments. If linac downtime is increased to account for availability of service parts and personnel, throughput is decreased by 6%, but conclusions remain unchanged. If a cobalt unit uses blocks instead of MLCs, throughput is reduced by 14-24% (1-3 block changes per fraction). Additionally, effects of machine utilization, IGRT usage, geographically specific cancer incidences (IARC data), fractionation schemes, and palliative or curative treatment goals were investigated.
**Discussion:** While additional aspects, including cost comparisons, dosimetric advantages, and personnel requirements remain to be addressed, this work establishes a framework for teletherapy implementation in low resources settings, and identifies power as the predominant influence on patient throughput.

**SP107.2 - The study of Total Marrow Irradiation Based on Rotational Intensity-modulated techniques**

**Author(s):** Shouping Xu1, Chuabin Xie2, Baolin Qu2, Wei Yu2, Wei Xu2, Xiaohu Cong2, Xiangkun Dai2

1Key Laboratory Of Particle & Radiation Imaging, Tsinghua University, Ministry of Education, Beijing/CHINA, 2Radiation Oncology, PLA General Hospital, Beijing/CHINA

Total body irradiation (TBI) is a special form of radiotherapy, generally as part of bone marrow conditioning regimens. Conventional TBI is difficult to achieve dose uniformity because of using the large field of simple technique. In recent years, tomotherapy technique has been used for TBI, due to delivering highly conformal and uniform target dose, and providing better normal structure avoidance. But this kind of technique isn’t widely used for its expensive cost. Volumetric-modulated arc therapy (VMAT) could achieve rotational intensity modulation based on the traditional accelerator and may obtain the efficient and accurate treatment with the imaging-guided device. The purpose of this study is to compare the dosimetric characteristics and efficiency of RapidArc and Tomotherapy in total marrow irradiation (TMI) for hematologic malignancies in order to get the reference data for the choice of clinical application. Eight patient plans were retrospectively designed and analyzed for RapidArc and Tomotherapy. Total bone marrow was contoured as clinical target volume excluding the cubitus and hand part, then plus a 3.0mm margin as planning target volume. The prescription was 12Gy in 10 fractions. ArcCHECK system was used for dose verification, and the safety and accuracy of clinical delivery would be evaluated. The results of this study showed that the two techniques could well achieve the target coverage. The conformity indexes of RapidArc and Tomotherapy were 0.54±0.05 vs 0.52±0.07 (p=0.45), but Tomotherapy plans have a visible advantage over RapidArc plans in the dose uniformity of target. The homogeneity indexes were 0.19±0.02 vs 0.13±0.02 (p=0.00). Tomotherapy plans showed better in sparing of the critical organs apart from the whole brain, oral, parotid gland, the small intestine, rectum, and the maximum dose of lens of Tomotherapy plans was reduced by 41% comparing to RapidArc plans. The MUs and treatment delivery time of RapidArc and Tomotherapy were 2608MU/560s vs 12842MU/891s. The gamma analysis passing rates for head-neck, chest-abdomen, pelvic were 98.9%±1.9%, 98.4%±1.8%, 97.4%±2.1% for RapidArc and 94.3%±1.5%, 96.5±1.2%, 94.1%±1.9% for Tomotherapy plans. This study shows that the two methods using RapidArc and Tomotherapy could achieve the acceptable dose of TMI, and the delivery efficiency of RapidArc was better than Tomotherapy. Two kinds of techniques are promising and can solve the clinic implementation of TMI.

**SP107.3 - IMRT and VMAT comparison for a case of bilateral breast carcinoma**

**Author(s):** Erick O. Montenegro1, Juan F. Lucero1, Rafael E. Lengua1, Luis A. Linares1, Milton E. Ixquiac2, Ricardo Contreras2

1Medical Physics, HOPE International Radiotherapy Center, Guatemala/GUATEMALA, 2Physics, Universidad de San Carlos De Guatemala, Guatemala/GUATEMALA

**Introduction:** A comparison was made between IMRT and RapidArc (VMAT) plans for a patient with bilateral breast carcinoma involving supraclavicular lymph nodes and skin. The prescription dose is 50Gy (25 fractions, 2Gy each), one of our goals was to maintain the organs at risk (OAR's) as low as possible.

**Objectives:**
- Select the best suited treatment modality for this case, taking into account the coverage to the PTV, the OAR's irradiation and the treatment delivery time.
- Evaluate the dosimetric parameters such as homogeneity, conformity index and monitor units.

**Methodology:** Four different treatment plans were created; three IMRT plans using 10, 11 and 16 fields and two full rotations VMAT.

All plans were optimized Eclipse (Ver.10.0) from Varian Medical Systems Inc. and delivered in a ClinaciX with Millenium Multileaf Collimator (120 MLC). The gamma evaluation was performed using the EPID AS500 and the ArcCheck from SunNuclear Corporation.

**Results:**

1: Comparison of dose distributions.
Conclusions:

It was decided to treat the patient with the VMAT plan. It is observed that it presents better PTV coverage, but more importantly the OAR’s receive less dose and it reduces drastically the treatment delivery time and the monitor units.

According to the gamma evaluation, all plans are equally reproducible.

SP107.4 - Measuring the Location and Dynamics of the Beam Spot and Field Centre on a Therapy Linear Accelerator in X-Ray Mode

Author(s): Victoria C. Foss2, Tyler S. Meyer2, David P. Spencer2

Introduction: On radiation therapy linacs the X-Ray source location, or beam spot, is critical to accurate treatment. Yet it is not measured. Instead, we accept that the vendors adjust symmetry and radiation-light field agreement. The beam spot will, therefore, be different for different photon energies. We set out to measure the location of the beam spot on a machine where the rad-light agreement was different for the 6 MV and 15 MV energies. We used images of the X-Ray projections of BBs at different source-to-object distances and 180° collimator rotations. We discovered that the beam spot actually moved during beam delivery. We believe this is due to the dynamic beam steering attempting to adjust beam parameters such as flatness and symmetry.

Methods: We mounted two 4 mm diameter Tungsten balls just off-axis on plastic trays in the upper wedge slot and in the cutout location of an electron cone. We took images at about 5 second intervals on a Varian Trilogy™ using an output rate of 100 MU/min in Service Mode on the linac and AM Maintenance High Quality mode on the aSi-1000 portal imager with a 4x4 cm field for both 90° and 270° collimator angles. We do not think the use of Service mode invalidated the use of our data for Clinical mode. Only the Collimator and Accessory interlocks were overridden. The images are analyzed using Doselab™.

Results: We observed that for 15X the field centre moved as much as 1.5 mm at the isocentre over the first 30 seconds of beam (see Figure), while our 6X beam moved about 1 mm. We also tested a stereotactic cone which showed field motion up to 0.3 mm at 6X over the first 30 seconds of beam (see Figure). This motion made it difficult to measure the location of the beam spot, since two separate images were required to determine its location. Assuming that sequential runs showed the same pattern, we paired the images to show that the beam spot moved about 0.15 mm for 6X, settling about 0.14 mm from the rotational axis. For 15X it moved 0.4 mm, settling about 0.12 mm from the rotational axis.

Conclusions: This means that beam spot size measurements assuming the beam is static may be incorrect. SRS delivery may be affected. Field symmetry and location will be time-dependent, so the QC time-scale should reflect clinical use. Investigations will continue on our other 8 linacs.

Materials and Methods:

The dose profiles along the two axes of an open and two filtered fields (filter A, and a thicker filter B) of the GB-500 were measured with a Standard Imaging (Middleton, WI) A12 ion chamber at 10cm depth in the centre of a 30×30×27cm³ (small) solid water phantom placed at various positions. These profiles were then calculated using the EGSnrc MC code (National Research Council, Canada) set to the conditions of the GB-500. Doses were calculated at selected depths in a continuous 360×120×27cm³ (large) water phantom and in the same small phantom as used in measurements. Over 60 billion histories were run on a CPU cluster to achieve an estimated dose uncertainty of <0.8% in the clinically useful field.

Results and Conclusions:

Measured and MC calculated longitudinal profiles are shown in Figure 1. For both filters, the beam flatness over 200cm treatment length for measured doses is approximately 3%. The beam flatness for MC calculated doses is slightly better for filter B (5%) than for filter A (6%). MC calculated doses (in both the small and large phantom) differ from the measured doses (in the small phantom) by a maximum and average of around 4% and 1% respectively, for all open and flattened fields. The agreement shows that the MC simulation faithfully models the GB500. Additional results showing prediction for new filter designs will be presented.
SP107.6 - Monte Carlo study for the design of a novel Gamma-Tomo SBRT system

Author(s): Grisel M. Mora¹, Omar Chibani², Ahmed Eldib², Jinseng Li², C.M Ma²

¹Institute Of Biophysics And Biomedical Engineering, University of Lisbon, Lisbon/PORTUGAL, ²Radiation Oncology, Fox Chase Cancer Center, Philadelphia/UNITED STATES OF AMERICA

Introduction: The 60Co beam emerging from the Gamma-Tomo source assembly was simulated in a previous study [1] and the authors reported the spectra of particles reaching the plane immediately (1mm) before the collimation system entrance. In the present work, we simulate the 60Co beam emerging from a novel Gamma-Tomo SBRT collimation system and calculate the output factors and dose rates for different source configurations and collimator sizes.

Methods: A Gamma Tomo system includes 13 60Co source capsules, source housing, a primary collimator and 4 different changeable collimators. The sources (6.22 mm of diameter) are located in 2 rows with different angles and distances to the longitudinal axis and the beams can be collimated to obtain four different circular field sizes at the isocenter (35 mm, 16 mm, 7mm, and 3.5mm). The BEAM-Monte Carlo [2] code is used to realistically model the collimation system geometry, including primary collimator and 4 different changeable collimators. The previously calculated phase space file [1] is used to transport particles throughout the collimation system to the patient plane for all of the changeable collimators of the Gama-Tomo System, and the respective phase space files of particles are stored at isocenter for each of the circular fields to be used as input of the GEPTS [3] to perform dose calculations. A newly designed geometry module is used to determine the dose distributions in a spherical polystyrene phantom with an 8cm radius centered at the isocenter.

Results: The characteristics of the particle spectra emerging from the collimation assembly are determined and the effect of the source-collimator position on the spectra reaching the isocenter found to be dependent on field size. We observed differences up to 5% between the energy spectra and fluence distributions calculated for different configurations of the source-collimator assembly. The effect of the source-collimator position is observed (up to 6%) on dose distributions calculated at isocenter and is dependent upon the size of the circular field.

Conclusions: The resulting data from the present study supports the machine design process and is valuable in building a well-represented source model for all sources to perform the dose calculations for all of the changeable collimators for this novel Gamma-Tomo system.

SP107.7 - A dosimetric evaluation of flattening filter-free volumetric modulated arc therapy for postoperative treatment of cervical cancer

Author(s): Fuli Zhang
Radiation Oncology Department, The Military General Hospital of Beijing PLA, Beijing/CHINA

AIMS: To compare flattening filter free (FFF) beams and conventional flattening filter (FF) beams in volumetric modulated arc therapy (VMAT) of cervical cancer after surgery through a retrospective planning study. MATERIALS AND Methods: For a cohort of 15 patients, VMAT plans of FFF beams and normal flattened (FF) beams were designed. The prescribed dose was 45Gy/1.8Gy/25f, 95% of the planning target volume received this dose. Doses were computed with a commercially available TPS using Monte Carlo (MC) algorithm. Plans were compared according to dose-volume histogram (DVH) analysis in terms of PTV homogeneity and conformity indices (HI and CI) as well as OARs dose and volume parameters. Results: FFF-VMAT was similar as FF-VMAT in terms of CI, but inferior to the latter for HI. No statistically significant differences were observed between FFF-VMAT and FF-VMAT in terms of pelvic bone marrow, small bowel, bladder and rectum. Conclusions: For patients with cervical cancer after hysterectomy, the FFF beam achieved similar target and OARs dose distribution as the FF beam. Reduction of BOT in cervical cancer is beneficial.
**SP108 - Patient and Occupational Dose Assessment**

**TRACK 05: DOSIMETRY AND RADIATION PROTECTION**

**SP108.1 - Radiation dose to patients from cardiac interventions performed using image intensifier, flat detector and novel flat detector systems**

**Author(s):** Roshan S. Livingstone¹, Anna Varghese¹, Paul V. George²

¹Radiology, Christian Medical College, Vellore/INDIA, ²Cardiology, Christian Medical College, Vellore/INDIA

**Background:** Radiation dose to patients from interventional cardiology are of concern whether it is being performed using image intensifier (II) or flat detectors (FD). There are very few reports on achieving reduced doses using novel FD systems with advanced real-time image noise reduction algorithms and optimized acquisition chain. This study intends to compare radiation doses from cardiac interventions performed using II, FD and novel FD systems.

**Design and Methods:** Coronary angiography (CA) and single stent percutaneous transluminal coronary angioplasty (PTCA) were performed using Philips Integris H5000 II, Philips Xper FD10 and Philips Allura ClarityFD10 mono plane systems (Philips Healthcare, Netherlands). The novel FD - Allura clarityFD10 was equipped with real-time noise reduction algorithms and optimized acquisition chain for dose reduction. Dose area product (DAP) was measured using DAP meter available in all systems. During interventions, low dose protocol with 0.4mm Cu filter for fluoroscopy and 0.1mm Cu for cine runs were selected in all systems.

**Results:** Tables 1 and 2 show dose related information for CA and PTCA performed in II, FD and novel FD systems. During fluoroscopic screening, DAP values were similar in all systems. However, during cine runs, a reduction of the order of 60% and 30% in DAP was observed in novel FD when compared to II and FD respectively. A 20 – 50% reduction in the overall doses could be achieved with the use of novel FD systems during CA procedures following standard imaging protocol.

**Conclusion:** Though all systems utilised stringent dose reduction strategies involving heavy filtration; significant dose reduction without compromising diagnostic image quality was observed using novel FD systems involving real time image noise reduction algorithm.

**SP108.2 - First National Occupational Radiation Dose Registry in Ministry of Health and its Validation: An Oman Experience**

**Author(s):** Arun Kumar L S, Rashid Al-Hajri, K Jaseer, Saeed Al-Kalbani

Medical Physics, Ministry of Health, Muscat/OMAN

In Ministry of Health (MOH), Oman; radiation is used for diagnosis, radiation therapy, bio-medical research and for the irradiation of blood & blood products. As per the IAEA Basic Safety Standards (2014), it is the responsibility of the employer to make arrangements for the assessment & recording of occupational exposures and for the workers’ health surveillance. Not only that, the records of occupational exposure for each worker must be maintained during and after the worker’s employment, at least until the worker attains the age of 75 years, and for not less than 30 years after cessation of the work. However, the current national radiation protection legislation...
of Sultanate of Oman does not mandate the recording of occupational doses or a national dose registry. To overcome this problem in MOH, Oman; we developed the first National Occupational Radiation Dose Registry (NORDR) for its workers.

This in-house developed NORDR - Centralised Dose Recording System (CDRS) - for the management of personal monitoring of radiation workers, is having about 1500 radiation workers in about 145 health facilities. Each one of them is monitored by issuing a Thermo Luminescent Dosimeter (TLD) every month through the CDRS by tagging the serial number of each TL dosimeter with the unique MOH staff number of each worker by post for a wear period of one month. Some of the above locations are very remote - few thousand kilometers away from the capital city, Muscat. End of every month, the TLD’s are collected back and processed for Hp(10) and Hp(3).

Upon estimation and recording of doses, individual and institutional dose reports are sent to the health facilities. The cumulative annual dose report of each worker is also dispatched from the NORDR facility to each worker.

CDRS also records age, sex, category of staff, section and department of staff, duration of work with radiation, dose received prior to joining MOH, any episode of an overexposure or any suspected over exposure, annual and cumulative radiation dose of each radiation worker etc. If a worker uses more than one TL dosimeter such as for forehead, lens, ring right, ring left etc; each will be accounted and accordingly dose will be estimated according to the type & the corresponding dose report will be generated. Also, the same software will handle the individual dose(s) of each worker on a monthly, quarterly, half-yearly, yearly basis and the dose history for the entire period of radiation job. CDRS will also perform the dose analysis of an individual worker, a group of workers in an institution and all the radiation workers available in CDRS as a whole. If a worker exceeds the annual dose limit or investigation level, the CDRS will alert accordingly. The details of our in-house national occupational radiation dose registry - CDRS - will be further discussed during presentation. This dose registry can be emulated by other countries those who do not have a national dose registry for their radiation workers especially for those who are having relatively smaller number of radiation workers.

### SP108.4 - A wireless personal dosimeter for Interventional Radiology medical personnel.

**Author(s):** Leonello Servoli, Massimiliano Paolucci, Maurizio Biasini, Lucia Bissi, Andrea Calandra, Bruno Checchi, Stefania Chiocchini, Roberto Cicioni, Elia Conti, Roberto Di Lorenzo, Anna C. Dipiato, Stefania Fabiani, Nevio Forini, Daniel Magalotti, Agostino Maselli, Daniele Passeri, Andrea Pantericci, Pisana Placidi, Maurizio Scarpignato, Andrea Scorzon

1Istituto Nazionale di Fisica Nucleare, Sezione Perugia/ITALY, 2AUSL Umbria 2, Foligno/ITALY, 3Università degli Studi di Perugia, Perugia/ITALY, 4Université degli Studi dell’Aquila, L’Aquila/ITALY, 5Università degli Studi di Modena e Reggio Emilia, Modena/ITALY, 6AUSL Umbria 1, Perugia/ITALY

A personal wireless active dosimeter prototype has been developed to be wearied by medical staff during Interventional Radiology procedures to obtain real-time measurement of the dose-rate.

It has been tested both on phantom and during several different medical procedures. It is battery powered with an autonomy up to 8 hours.

The dose-rate measurement is performed at a frequency of 5 Hz, and transmitted to the receiving station with no dead time and a packet error rate less than 1%. Even this small information loss could be recovered with simple data handling strategies, transmitting the integrated dose at the end of each procedure.

The dose-rate measurement capability, using a certified X-ray beam facility, is linear up to 400 microGy/s, higher than the rate diffused by the most demanding procedures, while there is virtually no upper limit on the dose measurement linearity, as long as the battery is working, because the sensor element is reset after each measurement ( > 1.5 Gy/h).

The sensitivity to diffused photon energy is below 10 keV.

The linearity of the response to an absorbed dose during medical procedures is shown in the following picture, where on the horizontal axis are reported the dose measured by the prototype and on the vertical axis the dose measured by the control dosimeter system (TLDs). Both systems have been calibrated simultaneously on the same certified X-ray beam.

### SP108.3 - Assessment of Patient and Staff Doses in Interventional Cerebral Angiography Using OSL

**Author(s):** Chryzel Angelica B. Gonzales, Center For Device Regulation, Radiation Health, And Research (cdrrhr), Department of Health (DOH) - Food and Drug Administration (FDA) Philippines, Manila City/PHILIPPINES

**Assessment of Patient and Staff Doses in Interventional Cerebral Angiography Using OSL**

Chryzel Angelica B. Gonzales, M.Sc.1,2 and Augusto A. Morales, Jr., D.Sc. 1,2

1The Graduate School, University of Santo Tomas, Manila, Philippines
2Center for Device Regulation, Radiation Health and Research, Food and Drug Administration, Department of Health, Manila, Philippines

**Abstract—** In interventional radiology (IR) procedures, radiation doses received by both patient and staff are relatively high. The objectives of the study are: (1) determine/measure entrance surface dose (ESD) to patient using nanoDot optically stimulated luminescence (OSL) dosimeter, (2) verify that patient doses do not exceed established international guidance levels set by IAEA and ICRP Report 103, as stated in the BSS, applied in the Philippines, (3) estimate the effective dose E to operator and using InLight OSL dosimeters, (4) estimate the annual effective dose E for the operator and staff performing interventional cerebral angiography procedure, (5) determine who among the staff have training in radiation protection in interventional radiology/cardiology, and if so, if such training is applied in practice, and (6) verify that staff doses do not exceed established dose limits set by the IAEA and ICRP Report 103, as stated in the BSS, applied in the Philippines.

Clinical data and technical factors were gathered from interventional cerebral angiography procedures (4-vessel angiogram/6-vessel angiogram) performed at the University of Santo Tomas Hospital (USTH). It was found that none of the ESD values approach the dose thresholds for induced skin injuries (erythema or epilation). The estimated weighted annual dose for all the interventional medical workers is 5.9 mSv which is lower than the dose limit given by the IAEA and ICRP Report 103, as stated in the BSS. However, the primary operator has exceeded the investigation level of 30% of the annual dose limit of 20 mSv (13.44 mSv in the case of research badge #3). The computation of the annual dose for this study was based on a survey for the maximum number of IR procedures performed per year.
SP109.1 - Development of a Thick Gas Electron Multiplier Based Multi-element Microdosimetric Detector

**Author(s):** Zahra Anjomani¹, Andrei R. Hanu², Sahar Darvish-Molla¹, William V. Prestwich¹, Soo H. Byun³

¹Medical Physics And Applied Radiation Sciences, McMaster University, Hamilton/Canada, ²NASA Goddard Space Flight Center, Greenbelt/United States of America

A prototype multi-element gaseous microdosimetric detector using Thick Gas Electron Multipliers (THGEM) has been designed and constructed for monitoring mixed neutron–gamma radiation fields. The multi-element design was employed to increase the neutron detection efficiency, particularly for weak radiation fields commonly encountered in radiation protection applications. Owing to the absence of wire electrodes, the THGEM multi-element detector offers flexible and convenient fabrication. The prototype THGEM multi-element detector consists of alternating layers of tissue-equivalent plastic hexagons and each layer houses an array of cylindrical gas cavity elements with equal height and diameter. The fundamental signal and stability performance of the THGEM detector was tested using a $^{244}$Cm alpha source and the detector responses to various neutron fields are currently under comprehensive investigation using the $^7$Li(p,n) neutron source at the McMaster Tandetron accelerator. A preliminary result on the neutron microdosimetric and absorbed dose responses of the prototype detector will be presented in contrast to the responses of a commercial detector.

SP109.2 - Development of a 2-D THGEM Microdosimetric Detector

**Author(s):** Sahar Darvish-Molla¹, Andrei R. Hanu², Zahra Anjomani¹, William V. Prestwich¹, Soo H. Byun³

¹Medical Physics And Applied Radiation Sciences, McMaster University, Hamilton/Canada, ²NASA Goddard Space Flight Center, Greenbelt/United States of America

Inspired by our prototype THick Gas Electron Multiplier (THGEM) detector [1,2], an advanced two-dimensional microdosimetric detector is currently under development at McMaster University. This detector aims to measure the spatial distributions of high and low linear energy transfer radiation doses simultaneously in mixed radiation fields, which will enable us to overcome the operational limitation of the classical tissue-equivalent proportional counters (TEPCs), particularly for high dose rate fields. Compared to the traditional TEPCs, wire electrodes were replaced by THGEM, which not only enhances the gas multiplication gain but also offers a flexible and convenient fabrication process for building two-dimensional detectors.

A prototype detector consists of an array of 3x3 gas cavities, equivalent to 9 TEPCs, each of which has a dimension of 5 mm diameter and length. By filling its sensitive volume with propane based tissue
equivalent gas, at a pressure of 167 torr, each detector simulates a spherical soft tissue of 2 μm in diameter. To process nine detector signals simultaneously, taking the overall cost, size and flexibility into account, we developed a multi-input digital pulse processing system using a modern microcontroller interfaced with an ADS807 12-bit sampling ADC with a sampling rate of 42 Msps. The prototype signal processor was tested using a NaI(Tl) detector and the test results have proven that it is faster than a traditional analogue system and a commercial digital system. Using the McMaster Tandetron 12L(p,n) accelerator neutron source, both signal performance as well as neutron dosimetric response of the detector have been extensively investigated. A preliminary test result will be presented.

In condensed media, the quantum wave nature of electrons may be non-negligible for simulation of sub-1 keV transport. These results within a simplified model of electron transport in condensed media suggest that electron transport is strongly affected by the structure of the medium and that inelastic scatter does not necessarily improve agreement between QM and MC simulations.

**SP109.4 - Investigation of the relations between absorbed dose to cellular targets and to bulk tissue for kilovoltage radiation using Monte Carlo simulations and cavity theory**

**Authors:** Patricia Oliver, Rowan Thomson

Physics, Carleton University, Ottawa/CANADA

Relationships between macroscopic (~1 mm) and microscopic (cellular) dose descriptors for incident photon energies between 20 and 370 keV are investigated using Monte Carlo (MC) simulations and cavity theory.

MC simulations of clusters of cells, single cells, and single nuclear cavities embedded in phantoms are carried out for various normal and cancerous tissues; cell (nucleus) radii range from 5 to 10 microns (2 to 9 microns). Results are compared to cavity theory predictions for the dose to a cavity of nuclear size and elemental composition embedded in a bulk tissue phantom (Dnuc), relative to the dose to the corresponding average bulk medium (Dmed). Large (LCT), small (SCT), and various intermediate (ICT) cavity theory approaches are investigated. The ICT approach (see figure) is a weighted sum of SCT and LCT contributions (stopping power and energy absorption coefficient ratios, respectively).

Approaches for computing the weighting parameter \( d \) include MC simulations determining the fraction of cavity dose due to electrons set in motion by photons interacting in the surrounding medium ('ICT: NFW method') and others involving Burlin’s approach (1969) where \( d = \frac{1-\exp(-\beta L)}{\beta L} \) with \( \beta \) given by \( \exp(-\beta \text{RCSDA})=0.01 \) or \( \exp(-\beta \text{RCSDA})=0.001 \) and \( L \) is the cavity’s mean chord length, taking RCSDA as the CSDA range corresponding to the most energetic electron or using a weighted sum of photoelectron and Compton electron components ('ICT:photo/Compton').

The ratio \( \frac{D_{\text{nuc}}}{D_{\text{med}}} \) varies considerably with tissue type, cell and nucleus size and elemental composition, and source energy. ICT predictions for \( \frac{D_{\text{nuc}}}{D_{\text{med}}} \) are highly sensitive to the method used to estimate the parameter \( d \). The figure provides example results for
the dose ratio $D_{nuc}/D_{med}$ for one cell model (cell and nucleus radii of 7.35 and 5 microns, respectively) in melanoma tissue; MC results give dose to the nucleus of the central cell in a multiple cell model. At low energies, LCT qualitatively predicts nuclear doses, whereas at energies above 50 keV, SCT predictions are reasonable. In general, over the range of energies and simulation geometries (tissues, cell types) considered, ICT with Burlin’s approach ($ICT: \exp(-\beta \frac{RCSD}{IA})=0.01$) provides the best estimate of $D_{nuc}/D_{med}$, resulting in an average discrepancy of 4%. However, no cavity theory method accurately predicts MC results over the entire range of energies and simulation geometries; thus, there is no general conversion method to obtain dose to the cellular nucleus from macroscopic dose descriptors. Further, neither dose to water nor dose to medium provides an accurate estimate of nuclear dose.

Results

γH2AX staining showed that the number of DNA DSBs was six-fold higher for 5 hour irradiated cells compared to controls. The incidence of 6 and more DSBs in an irradiated cell was 22 times higher compared to control cells. These numbers correspond to more than 5000 transmitted α-particles.

Conclusion

Timepix can be used effectively as a transmitted microdosimetry detector, providing high resolution images and excellent spatial resolution of detected α-particles. The relationship between the number of transmitted α-particles and the number of the DNA DSBs is being evaluated for us in targeted alpha therapy.

Figure 1: A) Experimental setup: Timepix chip was mounted above the A549 monolayer with an evaporated Ra-223 α-source underneath. B) Detection of transmitted α-particles using Timepix.

SP109.5 - Development of transmitted alpha particle microdosimetry using Timepix: Investigation of A549 lung carcinoma cells exposed to alpha particles irradiated from Ra-223

Author(s): Ruqaya Al Darwish, Alexander H. Staudacher, Eva Bezak

1Department Of Medical Physics, Royal Adelaide Hospital, Adelaide/AUSTRALIA, 2Centre For Cancer Biology, Translational Oncology Laboratory, Adelaide/SA/AUSTRALIA

Aim

To investigate the survival of A549 human lung carcinoma cells when irradiated with α-particles.

To correlate the number of DNA double-strand breaks (DSBs) per cell with the number of transmitted α-particles from Ra-223.

Materials and Methods

A549 cells were seeded at 15,000 cells on transwell inserts (0.14 cm²). The transwell system consists of two compartments: a larger well containing an evaporated Ra-223 source and an insert with a 10 µm thick polycarbonate membrane to which cells adhere.

The Timepix detector, Amsterdam Scientific Instruments, is a hybrid semiconductor pixel radiation detector. It consists of a pixelated silicon layer of 256 x 256 pixels (55 µm² each) bump-bonded to a CMOS pixel readout chip. Experiment setup is shown in figure 1 (A). Transmitted α-particles were detected and imaged with respect to seeded cells (figure 1 (B)). The quantitative correlation between the distribution of α-particle hits and cell damage was investigated for 1-5 hours irradiation times.

To assess the cell radiation damage, unirradiated (controls) and irradiated cell monolayers were stained with the DNA DSB marker γ-H2AX (green staining) and cell nuclei were counterstained with DAPI (blue staining). The number of DNA DSBs per cells after irra-
SP110.1 - Optical Navigation in Functional Neurosurgery

Author(s): Karin Wårdell
Department of Biomedical Engineering, Linköping University, Linköping/SWEDEN

Learning objectives:

Understand the basic principle of blue-light fluorescence microscopy

Be able to present two different fluorescence methods used in neurosurgery

Give examples of intraoperative navigation options used during DBS-implantations

Optical Navigation in Functional Neurosurgery

During the last decade, the use of optical techniques for navigation during neurosurgery has increased. Neurosurgical microscopes, introduced already in the 1950s, are today available with video recording and fluorescence imaging. Among these the blue-light setting is designed for visualization of malignant tumours by means of 5-aminolevulinic acid (ALA) [1]. In order to also quantify the fluorescence during tumour surgery, we have developed a handheld optical probe adapted to the requirements of the operating room [2]. The performance of the probe-system has been compared with fluorescence microscopy and biopsies and the results show that it is superior in detecting weak fluorescence when using the recommended microscopy-dose of ALA (20mg/kg). By combing the blue-light microscope and the hand-held probe both an overview of the operational field as well as the point specific fluorescence can be visualized.

Laser Doppler perfusion monitoring (LDPM) and imaging (LDPI), and diffuse reflectance spectroscopy (DRS) are other optical techniques currently under assessment as navigation support during neurosurgery. DRS allows for extraction of information from tissue chromophores and thus makes estimations of for instance saturation tissue of oxygenation possible [3].

With LDPI the cortical blood perfusion can be visualized whereas high resolution detection of differences in blood flow and tissue greyness can be achieved by LDPM. This dual function has been compared with fluorescence microscopy and biopsies and the results show that it is superior in detecting weak fluorescence when using the recommended microscopy-dose of ALA (20mg/kg). By combing the blue-light microscope and the hand-held probe both an overview of the operational field as well as the point specific fluorescence can be visualized.

Physical localized delivery based on electrospray process utilizes the bombardment of accelerated droplets containing the therapeutic molecule on targeted tissue, facilitating the entrance of the molecule into the cells. Electrospray process is based on Coulomb repulsion of charged particles, and to generate and accelerate the aerosol high electrical potential difference between a capillary and a counter electrode is required.

To transfer this method into clinical application single-port access instruments are needed providing the accelerating power and the fluid to the intraluminal region. The electrical field is applied by connecting the targeted tissue with ground potential, at the tip of the devices thus acting as counter electrode, while the high voltage is connected to the capillary axially placed within a working chamber. This configuration assures a predefined working distance and provides repeatable conditions of application.

Targeted gene or chemotherapeutic drug delivery offers a great potential for various diseases. In comparison to systemic delivery, side effects can be reduced and the quantity of delivered agent may increase. Also physical delivery is expected to reduce inflammatory and immunological reactions which often accompany targeted delivery utilizing viral vectors [1].

Physical localized delivery based on electrospray process utilizes the bombardment of accelerated droplets containing the therapeutic molecule on targeted tissue, facilitating the entrance of the molecule into the cells. Electrospray process is based on Coulomb repulsion of charged particles, and to generate and accelerate the aerosol high electrical potential difference between a capillary and a counter electrode is required.

To transfer this method into clinical application single-port access instruments are needed providing the accelerating power and the fluid to the intraluminal region. The electrical field is applied by connecting the targeted tissue with ground potential, at the tip of the devices thus acting as counter electrode, while the high voltage is connected to the capillary axially placed within a working chamber. This configuration assures a predefined working distance and provides repeatable conditions of application.

Based on described concepts, different instruments were designed and realized (Figure 1). First standalone devices (Ø10mm, adjustable working distance 0-10mm, rigid, fabricated with additive manufacturing) for endoscope assisted application and second miniaturized
A multi-modality intraoperative imaging system has been developed for hybrid cone-beam computed tomography (CBCT) and fluorescence diffuse optical tomography (FDOT). This translational research demonstrates that the use of CBCT spatial priors improves the quantitative performance of fluorescence tomography. Experiments with ICG inclusions embedded in liquid phantoms demonstrate that fluorescence signal of eGFP was detected after 24hrs incubation at 37°C using fluorescence imaging. GFP after electrospray expression indicates the successful transfection.

Both, the rigid and the miniaturized flexible electrospary instrument successfully transfected the plasmid into the cells, proving the suitability of electrospray for physical targeted delivery and providing a feasible concept of rigid and flexible electrospary instruments for gene therapy in clinical application.

SP110.3 - Cone-Beam CT-Guided Fluorescence Tomography for Intraoperative 3D Imaging
Author(s): Michael Daly, Nidal Muhanna, Harley Chan, Brian C. Wilson, Jonathon Irish, David Jaffray
Princess Margaret Cancer Centre, Toronto/Canada

A multi-modality intraoperative imaging system has been developed for hybrid cone-beam computed tomography (CBCT) and fluorescence diffuse optical tomography (FDOT). This translational research system is under investigation for clinical applications in head and neck surgery including oral cavity tumour resection, lymph node mapping, and free-flap perforator assessment. The fluorescence imaging system is configured for use with indocyanine green (ICG) using a collimated 760 nm laser diode and a 14-bit near infrared (NIR) camera. Frehand image collection in a non-contact geometry is achieved using a stereoscopic optical camera for real-time localization of the laser source and camera. Intraoperative CBCT images with sub-mm spatial resolution are acquired with a flat-panel C-Arm. FDOT is implemented using a finite element method for diffuse tissue optics (NIRFAST), with structural information from CBCT used directly in the optical reconstruction algorithm using Laplacian-type regularization (“soft priors”). The light rays from the laser source and camera pixels are geometrically projected onto the boundary elements of the tissue mesh using algorithms for ray-triangle intersection and camera lens distortion. Registration errors between real and projected boundary points are <2 mm for typical acquisition geometries. Surface flux is converted from CCD photon counts using free-space radiometry models and camera photon transport calibrations (e.g., filter transmittance, camera quantum gain, sensor noise). Pre-clinical studies using tissue phantoms and small animals are presented to characterize 3D imaging performance as a function of sub-surface fluorophore size, depth, and concentration. Experiments with ICG inclusions embedded in liquid phantoms demonstrate that the use of CBCT spatial priors improves the quantitative performance (<15% error, a reduction of 50% relative to no priors) in the tomographic reconstruction of fluorescence yield at depths <2 cm.

SP110.4 - An Optimal Motion Profile for a Wireless Endoscopic Capsule Robot
Author(s): Sina Mahmoudzadeh, Hamed Mojallali
Faculty Of Engineering, University of Guilan, Rasht/IRAN

Purpose: The inner parts of the GI tract such as the small intestine are inaccessible using conventional methods. We propose an optimal model of motion profile for a wireless endoscopic capsule robot (capsubot) for obtaining diagnostic data from the GI tract. Critical criteria such as the size and smoothness of the movement of the capsubot are taken into consideration for the optimization process, making it possible to fabricate the capsobut smaller in size, making it easier for the patient to swallow, and causing less discomfort during the procedure.

Methods: The legless capsubot model used in this work mainly consists of two parts: the inner mass and the capsule body which would contain the diagnosing equipment. The inner mass can move back and forth inside the capsule body. By applying a force to the inner mass in the proper direction, the capsule body can be moved forward or backward. An optimization model was developed for the motion of the capsubot which takes into account the limitations on the capsule body, such as shape, length and weight. The optimization model, uses non-linear optimization to minimize the power consumption and maximize the traversing distance given a limited battery source. Finally, a sensitivity analysis was performed to test the robustness of the proposed model to fabrication errors.

Results: The results showed 82% reduction in battery consumption for the movement of the capsubot compared to the other work in the literature, which allows the capsubot to be smaller than those in the literature. The results for simulation of the trajectory and the speed of the capsubot showed a smooth movement of the capsubot without any backward movement. Under the same conditions (same duration and available power for moving the capsubot) the capsubot moved a distance 89% longer than the best result of other work in the literature with the same power consumption. The sensitivity analysis results showed very low variability among the quality of movement of capsubot and distance traversed under small variations in different parameters of the capsubot such as size and length of the capsule body.
Conclusions: The results for the proposed model showed significant improvement in the motion of the capsulebot and the required power. Since the dimensions of the battery could be decreased due to the reduced required power, the model can be used to fabricate a potentially smaller capsulebot. This allows fabrication of a smaller capsulebot that could be swallowed more easily by the patient causing less discomfort, or a better use of the capsule space for adding additional features such as drug delivery and biopsy equipment.

SP110.6 - Orthogonal IR System for Instrumental tracking in Minimally Invasive Spine Procedures for training using Wiimote Technology
Author(s): Juana E. Martínez, Daniel Lorias, Arturo Minor Electrónica, CINVESTAV, México, D.F./MEXICO

In this paper we present a system for track the movements of the training instrumental in 3D space, using two infrared Cameras from two Nintendo Wii Remotes in order to evaluate the progress surgeons during the learning phase for making incisions and placement of screws in the spine throw minimally invasive procedures. The cameras are positioned orthogonally, and they detect the position of IR markers that are placed in the training instrumental.

SP110.7 - Use of a Patient-Specific Ventriculostomy Surgical Simulator to Develop a Model for Preoperative Risk Assessment Based on Measures of Anatomical Variation
Author(s): Ryan Armstrong, Roy Eagleson, Sandrine De Ribaupierre University of Western Ontario, London/CANADA

Insertion of a ventricular catheter—an external ventricular drain—is a common neurosurgical procedure. Though considered a simple procedure and often performed by residents, catheters are inserted blindly, most often without image guidance, relying on the surgeon’s spatial abilities and anatomical landmarking. The relatively high malplacement rates reported by some institutions reflect the difficulty. We used a virtual reality surgical simulator with patient-specific scenarios to examine the anatomical factors that influence user performance. Using objective metrics to quantify user performance and anatomical variations, we developed a model to predict malplacement risk based on measures of anatomical variation.

A diverse set of patient scenarios were created by segmenting the lateral and third ventricles from MR and CT images and incorporating the geometries into a custom ventriculostomy module within the NeuroTouch simulator. The simulator consists of a mannequin head with a pointing tool. Users are tasked to select a burr hole location and indicate the trajectory into the lateral ventricle. Metrics to evaluate user performance were devised to reflect clinical outcome using a single aggregate score. A model was constructed to estimate the difficulty of a given case based on the mean and variance of user performance. To examine the role of anatomical variations, we examined measures thought to influence performance, including ventricle volume, midline shift, Evan’s ratio and maximal width of the anterior horn. One neurosurgical expert and seven residents were recruited for a user study and each performed the surgical task of burr hole and trajectory selection a number of times on various cases. We found that anatomical variation in the simulator had a significant impact on user performance. Correlation with performance was seen for all anatomical measures, although the strongest predictors of performance were ventricle volume, midline shift and anterior horn maximal width. By determining the difficulty of each case based on user performance, we were able to produce a model to predict malplacement risk (based on targeting accuracy) using an optimized weighting of each anatomical variant measure considered.
SP111.1 - Ultrasound-induced heart rate decrease: Role of age in female rats

Objective:
Use of ultrasound in therapy has been increasing and new techniques have been developed as, for instance, in cardiac diseases. Animal models for cardiovasculardise disease support the hypothesis that female sex and/or the sex hormone estrogen may contribute to the sexual dimorphism in the heart and to a better outcome of cardiac diseases in females. Aging is associated with reduced responsiveness of many hormone receptors. The goal was to investigate the age-dependent changes in the cardiac system in female rats exposed to pulsed ultrasound that may benefit therapeutically with heart rhythm abnormalities.

Methods:
Transthoracic ultrasonic exposure experiments were divided into two female Sprague-Dawley rat groups (n=5 ea): Group 1: Five 3-mo-old 200-250-g rats and Group 2: Five 24-mo-old 250-400-g rats. The ultrasonic exposure protocol was the same for both groups: 3.5 MHz pulses of 2.0 MPa peak rarefactional pressure amplitude (equivalent to spatial peak intensities of 133 W/cm²), variable pulse repetition frequencies (6, 5, 4, 5, 6 Hz), 10-s each sequence (0.5% duty factor), see Figure. Cardiac conditions were evaluated before (at baseline) and at 3 and 15 min after ultrasonic exposure ceased (3 and 15 min results normalized to each rat’s baseline values).

Results:
Group 1: at 3 and 15 min, respectively, the heart rate decreased 12% and 15%, and the cardiac output decreased 16% and 14%. Group 2: at 3 and 15 min, respectively, the heart rate decreased 12% and 15%, and the cardiac output increased 14% and 15%. There was no significant difference between the younger and older rats for the heart rate or for the cardiac output.

Conclusions:
Pulsed ultrasonic exposure caused similar decreases in the heart rate and cardiac output in the two rat-age groups, that is, there were no age-dependent differences in the cardiac system of young and old female rats stimulated by pulsed ultrasound. The results are promising for therapeutic application in cardiology as treatment for heart rhythm abnormalities in women of different ages. This work was supported by NIH R37EB002641.

SP111.2 - Low cost pulsed wave Doppler ultrasound system for vascular studies

Objective: To implement a Doppler ultrasound system with user interface for visualizing the blood flow profile relative to Doppler shift spectrum. Data visualization occurs by RGB mode with 9 bits color depth, 8 bits for velocity resolution and 7.5 ms of time resolution. The visualization of the sonogram is at 130 frames/s. Digital processing and user interface are implemented on a Xilinx Spartan-3E FPGA. This low cost alternative for diagnosing vascular pathologies on superficial vessels helps to prevent and assist the high number of cases affected by vascular diseases in Cuba.

Keywords — vascular diseases, ultrasound, FPGA, low cost.

SP111.3 - Real-Time Three Degree-of-Freedom Measurement of Catheter Motion for Input to a Robotic Catheter Navigation System

Objective: Commercial robotic catheter navigation systems (RCNS), used for many types of cardiac ablation therapy, enable the interventionalist to remotely manipulate a catheter’s position. Typically, the interventionalist operates the robotic systems unnaturally with a provided user interface that is not instinctive, often including a joystick-based controller. Specialized training is required to operate these systems, which may lead to future dependence on this technology. An intuitive solution was previously developed to facilitate translation form conventional to robotic intervention [1]. This device detects axial and rotational changes of a master-side catheter and although inherent to the interventionalist, its use in contemporary RCNSs is limited because modern interventional catheters are steerable, permitting catheter tip deflection. To address this, we have developed a master-side input device that detects motion changes in all three positional degrees-of-freedom.

Methods: The input device enables direct manipulation of an ergonomic master-side catheter handle. A shell of a recycled steerable
Y. Thakur et al., precision and dexterity. The catheter handle assembly is then mounted on a custom linear motion stage whereby a rack and pinion mechanism coupled to another encoder detects axial motion. A dedicated electronic system with a powerful microcontroller provides quadrature encoding and robotic motion scaling to enable higher levels of precision. A wireless module provides position streaming to a slave robot. The design of the input device provides a calculated axial resolution of 13 μm and both rotational and deflection resolution of 0.18°. The accuracy of the input device was evaluated using an optical tracking system. Five 30-second motion profiles were manually imposed on each degree-of-freedom. Position data provided by the embedded system and the tracking system, were then compared for their mean error.

**Results:** The input device, depicted in the image below, shown to have an absolute mean error in the axial direction to be 0.44 ± 0.33 mm, rotary direction to be 0.41 ± 0.15°, and tip deflection to be 0.54 ± 0.43°. The on-board embedded system enables reliable, high-speed data transmission for optimal master-slave robotic control and permits selectable motion scaling.

**Conclusion:** We have developed and evaluated an instinctive master-side input device that can be used with an RCNS to fully manipulate a slave-side steerable interventional catheter with high precision and dexterity.

**SP111.4 - Pulse Wave Velocity as a Function of Cuff Pressure – Extra Information About the Cardiovascular System**

**Author(s):** Akos Jobbágy, Peter Nagy

Measurement And Information Systems, Budapest University of Technology and Economics, Budapest/HUNGARY

High blood pressure (BP) is one of the biggest global health risks. Non-invasive methods determine only the momentary value of systolic- and diastolic BP. Knowing arterial rigidity would provide cardiologists with invaluable extra information.

A Home Health Monitoring Device, HHMD, was developed at the Dept. Measurement and Information Systems, Budapest University of Technology and Economics. HHMD inflates and deflates the cuff slowly (6 mmHg/s) and records also ECG and photoplethysmographic signal (PPG) at both index fingertips. Among other parameters the pulse wave transit time, PWTT is calculated. Measured from a healthy senior person, Figure 1 shows a typical PWTT – cuff pressure (CP) curve. Occlusion with the cuff causes temporary alteration in the dynamic properties of the brachial artery. The alteration can be characterized by the change of PWTT.

**Fig. 1.**

The slope of the PWTT – CP curve is characteristic for the cardiovascular system. We determined the CP belonging to the steepest change. During inflation it is denoted by *dup*. PWTT was averaged for 8 s with CP=0 before (PWTTbefore) and after (PWTTafter) inflation and deflation. The ratio of the two PWTT values is ΔT Ratio=PWTTbefore/PWTTafter.

170 were selected and analyzed from more than 1500 recordings taken from patients who underwent open-chest cardiac surgery and also from young- and senior healthy control persons. The results confirm that the PWTT – CP function provides extra information about the state of the brachial artery. Based on our research we suggest three parameters to quantify this information.

The difference between *dup* and DBP: For all the three tested group *dup* correlates with DBP. The difference is smallest for the young healthy group. Values for the senior healthy persons and for the patients are similar.

The change of PWTT: In most cases PWTT is greater after than before occlusion, thus ΔT Ratio < 1. It can be interpreted that occlusion temporarily increases the elasticity of the brachial artery. For patients ΔT Ratio can exceed 1. The value of ΔT Ratio is an indicator of arterial rigidity; it correlates neither with SBP nor with DBP.

Slope of increase of PWTT during inflation: There is almost no difference among tested persons regarding the slope of increase of PWTT during inflation when CP exceeds *dup*. However, there are two patients who sometimes produced much higher values than the maximum of all other tests (6 s/mmHg). This indicates momentary increased rigidity of the arterial wall.

**SP111.5 - Cardiac Output estimation through Impedance Cardiography using reconfigurable hardware.**

**Author(s):** Leydy M. Alvero González

Bioengineering Department, High Polytechnic Institute Jose Antonio Echevarría, Havana/CUBA

Impedance Cardiography allows the noninvasive determination of cardiac output quickly and continuously. Cardiac output provides vital information for evaluating and analyzing the hemodynamic information in patients who are in critical medical conditions. A distribution of current-injection electrodes is used to sense changes to pulsed voltage changes that are proportional to the thorax bioimpedance. The acquired signal combines basal impedance component with dynamic tissue components. It is the resulting product of an amplitude modulation with frequency components located on either side of the frequency component of the injection signal. A quadrature demodulation stage is used for translation to baseband of the signal in order to preserve amplitude and phase information. Digital signal processing is implemented on FPGA, allowing high flexibility during the research process.

**SP111.6 - Microfluorimetry System Instrumentation for Ca^{2+}−**
Associated Fluorescence Imaging of Cardiomyocytes in Response to High Electric Fields

Author(s): Marcelo Zoccoler¹, Pedro X. Oliveira²
¹Faculty Of Electrical And Computing Engineering, University of Campinas, Campinas/BRAZIL, ²Center of Biomedical Engineering, University of Campinas, Campinas/BRAZIL

The defibrillation is the only effective therapy against ventricular fibrillation. Although a common clinical procedure, this technique also harms healthy cells by means of electroporation, possibly re-introducing arrhythmias. In order to study how myocytes respond to high electric fields (E), scientists commonly use fluorescent dyes in sophisticated and expensive microscopes. These devices produce high quality data, but they are sometimes financially unreachable. We have developed an artisanal microfluorimetry system employing some pieces from deactivated medical equipments. The system proved successful as we could generate quality fluorescence images of isolated adult rat cardiac myocytes loaded with Ca²⁺-associated fluorescent dye Fluo-3 and subjected to monophasic high intensity E. Cells with major axis parallel to E direction were selected. Using regions of interest (ROIs) analysis, we verified that fluorescence variations in ROIs facing the electrodes are bigger and asymmetric, with higher variations at the side towards the anode.

SP111.7 - A practical device to warn on impending syncopal episodes

Author(s): Michael Cheng¹, Venkatesh Thiruganasambandamoorthy¹, Hilmi R. Dajani², Miodrag Bolic³
¹Biomedical Engineer, ottawa/ON/CANADA, ²Emergency Physician, Ottawa Hospital, Ottawa/CANADA, ³School Of Electrical Engineering And Computer Science, University of Ottawa, Ottawa/ON/CANADA, ⁴School Of Electrical Engineering And Computer Science, University of Ottawa, N/CANADA

Syncope (fainting) can lead not only to serious personal injury but also can endanger public health as when the sufferer is driving a car. An electronic monitoring device can help to minimize syncopal events due to cardiac rhythm changes. This kind of devices will greatly enhance the ability of the patient to take immediate action to safeguard personal and public health.

On the current consumer market, there are numerous heart rate monitoring devices catering for sports use with sophisticated software support; however such devices are not specific to individual patient’s needs. On the other hand, ample devices are available to monitor and record various patient data to be analyzed by proprietary clinical software catered for physician use; but such devices are relatively expensive, sold only to physicians, and the data are interpreted “off line” (by the physician).

This paper proposes a simple device to be worn by sufferers of cardiac arrhythmia to provide online (instant) warning signals directly to the wearer on impending fainting. The sufferer could act immediately to stop physical activities, sit, lie down, or stop the car etc. and so help prevent potential injury to the sufferer or to others. The device concept is based on physiological findings that when the time interval between successive heart beats (the RR interval) is

SP111.8 - Robust Blood Pressure Monitoring in Atrial Fibrillation Patients

Author(s): Saif Ahmad¹, Izmail Batkin¹, Miodrag Bolic², Hilmi R. Dajani¹, Voicu Z. Groza¹, Sanjeev Chander³
¹University of Ottawa, Ottawa/CANADA, ²Ottawa Cardiovascular Centre, Ottawa/CANADA

Background Blood pressure (BP) is an important vital sign characterizing cardiovascular health. Therefore, hypertension/hypotension diagnosis and management through accurate monitoring is critical for reducing risk of life-threatening conditions like stroke. Automated non-invasive BP (NIBP) devices are increasingly recommended in clinical practice. However, these devices tend to be unreliable in patients with chronic conditions like atrial fibrillation (AF) and obesity [1] – resulting in inefficient BP management and hence increased risk [2]. Unreliability arises because NIBP monitors estimate BP by analyzing arterial pulses alone and these patients may present weak, erratic, and/or unpredictable arterial pulses.

Method/Results Health Parametrics Inc. (HPI), a University of Ottawa spinoff, is investigating novel technology for increasing the accuracy of automatic NIBP estimation. Briefly, we have developed a novel yet simple method for simultaneous acquisition of electrocardiogram
SP112 - Instrumentation

SP112.1 - Adaptation of Surgical Instruments for the Removal of Bladder Tumours

Author(s): Spencer C. Barnes¹, Duncan E.T. Shepherd¹, Daniel M. Espino¹, Richard Viney², Prashant Patel², Richard T. Bryan²

¹Mechanical Engineering, University of Birmingham, Birmingham/UNITED KINGDOM, ²School Of Cancer Sciences, University of Birmingham, Birmingham/UNITED KINGDOM

Background: Transurethral resection of bladder tumour (TURBT) is the gold standard in non-muscle invasive bladder cancer removal. The tumours are removed piecemeal and this is thought to be a key reason for the high recurrence rate of up to 78% at 5 years.

Aims: A novel device has been designed to facilitate a decrease in this high recurrence rate by creating a sealed environment in which the surgeon can resect a tumour. This device aims to arrest the spread of cancer cells to the rest of the bladder wall.

Methods: Shape memory metal (Nitinol), 3D printing and latex have been used to create an actuating cone which can press against the bladder wall, surrounding the tumour. This design, in the open state, can be seen in figure 1 around a resectoscope, the device currently used for removing bladder tumours. Shape memory alloys (SMAs) such as Nitinol exhibit the property of solid phase change when heated and as such are able to move to a pre-trained shape. Nitinol wires were ‘trained’ at 550 °C in a steel jig at 30°. These wires were then sequentially placed in a 3D printed housing and soldered together in a series configuration. Subsequently, liquid latex was painted onto the wires using a mould, and allowed to dry. After being initially deformed to a closed state the device was then able to open when heated.

Testing: The device was actuated successfully using a 2.6 ampere 10 volt supply in liquid environments at 37 °C using custom made testing apparatus. Despite the extra heat loss due to the liquid environment the device was still able to open. The ability of the device to seal was also successfully tested with blue dye.

SP112.2 - A compact gantry based on pulse powered magnets for a laser-based proton radiotherapy

**Author(s):** Leonhard Karsch1, Thomas Hermannsdörfer2, Florian Kroif3, Umar Masood2, Michael Schürer1, Jörg Pawelke2

1TU Dresden - Oncoray, Dresden/GERMANY, 2Helmholtz-Zentrum Dresden - Rossendorf, Dresden/GERMANY

**Purpose:** The new approach of particle acceleration by high intensity lasers may provide size and cost reduction for proton facilities. However, laser-driven proton beams are characterized by intense and short (few picoseconds) pulses with low repetition rates, high energy spread and large beam divergence. In addition to more compact accelerators due to the short acceleration length of few micrometers, also more compact beam transport systems are possible. The beam pulse structure enables more compact gantries by the use of pulse powered magnets without iron core, but much higher magnetic field strengths. Using pulsed magnets, the magnetic field is only generated for a short time period but still sufficient long for the transport of a proton pulse.

**Method:** First, a gantry was designed regarding laser accelerator specific requirements like a proton capturing element and an energy selection system. Secondly, prototypes for every type of pulsed magnets necessary for the gantry - solenoid, dipole and quadrupole - were designed and realized. Thirdly, these prototypes were experimentally characterized at a pulsed 10 MeV proton beam of a tandem accelerator. This beam is well defined in energy and intensity, the pulse duration is arbitrary adjustable down to 1 microsecond which is still longer than the pulse duration of laser driven beams. Therefore, it allows to test the ion optical behavior at low electrical risks, i.e. at reduced magnet current.

**Result:** A gantry for laser driven proton therapy was designed being much smaller than existing devices. A radius of 2.5 m and a length of 3 m is achieved by deploying high magnetic fields of up to 40 T inside the solenoid, up to 10 T inside the dipole and a magnetic field gradient of up to 300 T/m in the quadrupole. The achieved magnetic pulse durations with these prototypes are approximately 1 ms. The duration during which the field is constant is about 100 microseconds. Each of the individual magnets, as well as their combination to a pulsed beamline, show the expected ion optical properties like focussing and bending.

**Outlook:** After an adaptation of the setup, further experiments at clinical relevant proton beam energies (up to 230 MeV) will follow. For this purpose, the proton beam from the conventional cyclotron at a facility in Dresden recently put into patient treatment, has been adapted to deliver pulsed beams to an experimental bunker. The work is supported by the german government BMBF (no. 03Z1NS11).

SP112.3 - Developing a pH Responsive Mesh as a Smart Skin Wafer in Ostomy Appliances

**Author(s):** Anna McIlstr, James Davis

Nibe - Computing & Engineering, Ulster University, Newtownab-ey/UNITED KINGDOM

**Purpose:** Despite notable advancements in the management and treatment of ostomies over the past number of years, one problem still persists; peristomal skin complications (PSCs). The erosion of the skin directly underneath the skin wafer as a consequence of exposure to stoma fluid can lead to debilitating irritation and ulceration and is one of the most common post surgical complications. In the US alone, it is estimated that over one million patients deal with the routine of ostomy care, the majority of which will have, at some point, suffered from a PSC. Despite requisite pre and post-operative education for new patients, PSCs continue to be a perennial issue with incident rates ranging from 10-70%.

**The present communication outlines progress towards the design of a smart wafer system that can actively monitor the skin condition and respond accordingly to minimize the onset of irritation dermatitis. A conductive, mechanically flexible mesh incorporating poly-L-tryptophan is detailed and its modification to yield a pH sensitive diagnostic layer is outlined. The system has been characterized and its potential integration and application in stoma appliances is critically appraised.**

SP112.4 - Development of a smart needle integrated with a micro-structured impedance sensor for the detection of breast cancer

**Author(s):** Niall T.P. Savage1, Brian D. O’Donnell2, Martin J. O’Sullivan3, Eric J. Moore1

1Life Science Interface, Tyndall National Institute, Cork/IRELAND, 2Department Of Anesthesia, Cork University Hospital, Cork/IRELAND, 3Department Of Surgery, Cork University Hospital, Cork/IRELAND

**The aim of this research is to develop a novel medical device for the detection of breast cancer within the clinical setting. Breast cancer is the second most common cancer in women worldwide and the use of population-based screening programmes has increased the demand for more sensitive and specific detection tools to limit the number of patients being misdiagnosed or over-treated. This research will focus on the development of a minimally invasive diagnostic probe for the determination and localisation of cancerous tissue within the structure of the breast. Gold microelectrodes fabricated on a silicon substrate were developed in Tyndall National Institute and used to obtain electrical impedance recordings from ex vivo tissue samples of both animal and human origin. Functional prototype devices have been produced using both photolithogra-
Chronic obstructive pulmonary disease is the 4th leading cause of death worldwide. Extracorporeal lung assist devices that promote oxygenation and/or CO2 removal, like the Novalung interventional lung assist device (iLA®), can improve lung protection and increase quality of life [1]. As a drawback these systems limit patient mobility. In addition, longterm use is frequently accompanied by thromboembolic complications and device fouling due to inappropriate material characteristics of the blood contacting surfaces. Our goal is to develop the first wearable miniaturized lung assist device with improved surface properties [2].

Methods

We developed prototypes of new miniaturized hard- and software components, as well as a suitable carrying system. We also designed a new, disposable gasexchange unit with optimized geometry to minimize hemolysis and thrombogenicity. Hemolysis and gas exchange performance tests were carried out in vitro and validated in a porcine model.

To improve the hemocomaptibility of the gas exchange material Polymethylpentene (PMP), we seeded human dermal endothelial cells onto PMP hollow fibers, either coated with heparin/albumin, or covalently functionalized with heparin/RGD. Seeding efficiency and cell coverage were analyzed microscopically using live/dead staining and staining for van Willebrand factor.

Results

We successfully miniaturized all hardware components and developed a new design of the gas exchanger to improve blood distribution, while maintaining adequate gas exchange in vitro and in vivo. Following seeding of stacked PMP fiber mats, the endothelial cells formed a confluent monolayer on the fibers, which was preferentially retained for 5 days on the heparin/RGD coated fibers under both static and dynamic in vitro testing conditions in a new bioreactor system.

Conclusion

We successfully designed and implemented a miniaturized wearable lung assist device, which is currently being tested in a porcine model. Importantly the gas exchange property of the miniaturized device are adequate to provide significant respiratory support. Future studies will test these devices in a first in man trial.

SP112.6 - Development of a Low Cost Spectrometer for Studies of Diffuse Reflectance with Dermatological Science and Applications

Author(s): Gerardo S. Romo-Cardenas, Sydney Dominguez-Dominguez, Rustiel Dominguez-Dominguez
School Of Engineering, Montemorelos University, Montemorelos/ MEXICO

From an optical perspective, skin with all its layers and surfaces are made from different tissues that have different or unique pattern of reflectance, which could help to differentiate normal or healthy tissues from those with a presence of any type of injury or pathology. The application of optical tool for the characterization of bio- tissues have gained importance due to its noninvasive nature.

In this work it is proposed to conduct a study to develop an inexpensive spectrometer and a light source of broad spectrum; as well as the protocol that would allow the exploration of diffuse reflectance of colloids with the intention of develop a tool that could be used to identify any type of pathology. In this paper, the preliminary results of the study, involving the development of the light source, a low-cost spectrometer and the measurement and analysis protocol to explore the feasibility of implementation in areas of biomedical science areas are discussed.

Beside the development of the system, agar and dyed gelatintis-
sue phantoms were used in order to study the performance of the system.

Results show a good consistency in the performance of the developed spectrometer, in its capability to acquire the diffuse reflection from the tissue samples. As well, in accordance to the irradiated wavelength and the amount of dispersion induced in the tissue phantom. Still, results cannot be conclusive in order to determine significate differences that could lead to the application of this technology in health applications, it is expected to obtain a better specificity with future work.

**SP112.7 - Correctness of bioimpedance data for body composition obtained by BIA approach in various external conditions**

**Author(s):** Jan Hlušík¹, Lenka Lhotská¹, Jan Kříž²

¹Cybernetics, Czech Technical University, Prague/CZECH REPUBLIC, ²Department Of Physics, Faculty of Science University of Hradec Kralove, Hradec Kralove/CZECH REPUBLIC

This paper presents our ongoing research in a field of body composition obtained by body impedance analysis. In this work we were focused on changes in bioimpedance in dependence on change of measurement external conditions. This paper also deals with question if data obtained from this method are enough informative with ought any information about the performed measurement. We discovered that it is crucial to have information about the whole measurement procedure and that operator that is performing such measurement should know exact type of device that is used for measurements. Influence of specific conditions did not statistically changed results of calculated values. However in directly measured values resistance and reactance at high frequencies (250 kHz and 500 kHz) were found statistically significant changes (P=0.05) for highly conductive gel. Overall was concluded that external conditions that can be normally encountered at laboratories do not have effect on obtained values. However it is important to know which device was used so the set of used equations are comparable.

**SP113 - Information Technologies in Healthcare Delivery and Management: Part 1**

**SP113.1 - Technologies for Patient Self-Care of Chronic Illness: Development and Evidence.**

**Author(s):** Joseph A. Cafazzo

Centre For Global Ehealth Innovation, University Health Network, Toronto/CANADA

The global plight of chronic illness has affected healthcare systems around the world. The delivery of care for those who need it most is not sustainable without a re-evaluation of enabling patients and their informal caregivers with the ability to perform self-care. Technological innovation in this area is showing great promise with the advent of mobile devices and wearables, but is not without the challenges of design, implementation, and a lack of clinical evidence. The keynote will outline addressing these challenges and the emerging evidence that shows the untapped potential of patients when given the opportunity for self-care facilitated through technology.

**SP113.2 - A mobile monitoring tool for the automatic activity recognition and its application for Parkinson’s disease rehabilitation**

**Author(s):** Jorge Cancela, Matteo Pastorio, Eugenio Moreno, Maria T. Arredondo Waldmeyer

Life Supporting Technologies, Universidad Politecnica de Madrid, Madrid/SPAIN

In order to perform a continuous monitoring of patients in their daily lives, it is the need to contextualize the collected data coming from the patients. In this sense, the identification of the Activities of the Daily Life (ADL) carried out by the subjects is essential to understand and to put in context other data linked to the monitoring disease itself. This work was aimed at using the accelerometers integrated in most of the current available smartphones to build an automatic activity recognizer based on the signal coming from this sort of sensors. The validation carried out showed the impact of the frequency sampling in the classifier performance as well as the impact in the battery usage. Finally, it suggested that the use of one second as sampling period is a fair trade-off between accuracy in the classification and power saving.

**SP113.3 - My Patient: An Electronic Patient Information Management System**

**Author(s):** Satish Jaywant¹, Qaiser Muhammad²

¹Uhn International Program, Princess Margaret Cancer Center/University Health Network, Kuwait City/KUWAIT, ²University Health Network, Toronto,Canada, Kuwait/KUWAIT

Princess Margaret Cancer Center/University Health Network (UHN), Toronto, was approached to improve cancer services over a period of five years at the Kuwait Cancer Control Center (KCCC), Kuwait. As an integral component of this project, a computerized appointment scheduling system was implemented to reduce patient wait times, improve patient satisfaction and efficiency. It also provided an opportunity for data collection, tracking and management of resources. For this purpose, an electronic patient management system called “My Patient” was developed that will allow users to
become familiar with the basic steps and processes of creating, accessing and updating patient records. UHN Kuwait Information Management/Information Technology teams performed the gap analysis and requirements for the KCCC outpatient department workflows. It then worked closely with KCPC clinicians to finalize the clinical engagement, project governance and implementation plan. An in-house outpatient department scheduling module for KCCC was built. The pilot was launched May 2014 for 2 months in the gastro-intestinal site and has now been implemented for Radiation Oncology.

The tasks and functions in My Patient cover four distinct areas: Registration: Staff within the Medical Records Department has access to register patients, create new patient files and modify patient demographic information. Other users must contact Medical Records to have these functions performed.

Scheduling: This functionality is available within the outpatient departments to staff with appointment booking access. Any other My Patient users can only view schedules whereas booking, updating and cancelling appointments is limited to scheduling users only.

Laboratory Ordering: The cytology laboratory staff has access to the laboratory management tool for laboratory order entry, specimen number generation and specimen label printing.

Administrative: The supervisory staff within each department has administrative access to correct entry errors within their department.

Various safety and patient confidentiality features are in place in this tool. As an example, every staff member accessing My Patient for clinical or administrative purposes has a unique user name and password. This presentation highlights the application of My Patient to Radiation Oncology.

SP113.4 - Hom-e-call – An enhanced fall detection system based on accelerometer and optical sensors applicable in domestic environment

Author(s): Daniel Wohlrab1, Markus Heß2, André Apitzsch2, Mandy Langklotz3, Andreas Schwarzenberger1, Sebastian Bilda1, Henry Schulz2, Gangolf Hirtz2, Jan Mehner1

1Professorship Of Microsystems And Biomedical Engineering, Technische Universität Chemnitz, Chemnitz/GERMANY, 2Professorship Of Digital Signal Processing And Circuit Technology, Technische Universität Chemnitz, Chemnitz/GERMANY, 3Professorship Of Sport Medicine And Sport Biology, Technische Universität Chemnitz, Chemnitz/GERMANY

A reliable detection of falls is an important challenge for applications of ambient assisted living. Especially for elderly people living autonomously at their home, such a system would help to treat possible injuries faster. Most of the currently used systems are only based on the analysis of the movement data recorded by a wearable device. In this study an automatic fall detection system is developed that can be installed in domestic environment. Based on an accelerometer fixed to the body and optical sensors mounted on the wall, the fusion unit analyses the actual posture of the patient and detects fall events. By means of simulated fall scenarios performed by young athletes, the overall system performance is tested. To identify the false alarm rate of the fall detection system elderly people have performed activities of daily living in a furnished test flat. The combined system approach can be used to improve conventional fall detection algorithms.

SP113.5 - An Algorithm Based on Voice Description of Meal for Insulin Dose Calculation to Compensate Food Intake

Author(s): Piotr Fołtyński1, Piotr Ładyżynski1, Ewa Pankowska2, Karolina Mazurczak2, Karolina Migdałka-Musia2

1Nalecz Institute of Biocybernetics and Biomedical Engineering, Polish Academy of Sciences, Warsaw/POLAND, 2Department of Pediatrics, The Institute of Mother and Child, Warsaw/POLAND

Diabetes may lead to serious complications when blood glucose levels are not maintained in safe ranges. Proper insulin dosing is crucial in good metabolic control, however it is not easy for all patients. There are some computer applications supporting insulin bolus calculation based on the meal composition, but they may be difficult to use for some patients. Our team decided to developed a voice-driven system helping patients in calculation of the proper insulin dose for food intake compensation. The system consists of several software applications (on smartphone and MS Windows server) working with developed language dictionaries and with nutrient database. The speech recognition software was trained with sets of words from meal descriptions. The algorithm for transition from the text description is based on language dictionaries with variety of food item descriptions related to one product in nutrient database. The system calculates the number of insulin units for patients using insulin pen or delivery time and number of insulin units for patients with insulin pump. The algorithm for insulin dosage works not only on the basis of the amount of carbohydrates, but also takes into consideration protein and fat content in the meal. The system was successfully tested on the group of 34 subjects achieving 92.3% of correctly recognized food descriptions in the first try. The overall percentage of fails in recognition was 1.5%.

SP113.6 - Building neuroscientific evidence and best practices in active and healthy aging

Author(s): Panagiotis D. Bamidis

Medicine, Lab Of Medical Physics, Aristotle University of Thessaloniki, Thessaloniki/GREECE

Supporting the elderly by means of technology has recently taken the form of monitoring the elderly in an unobtrusive way. The latter is linked with the task of installing various devices inside the home as well as requesting the elders to wear specific garments (e.g. watches, bracelets etc) or being trained by means of cognitive and physical exercise games (serious gaming: exergaming). The latter forms a contemporary trend within the field of Active and Healthy Aging (AHA). Serious games for elderly healthcare provide a promising and novel way to promote the well-being of senior citizens. However, to fully understand the underlying mechanisms as well as to accumulate scientific evidence for such approaches, we argue that one needs carefully designed neuroscientific experiments, along the usual batteries of neuropsychological tests and subjective measures like quality of life questionnaires.

In the past 6 years we have been using a comprehensive protocol of EEG recordings pre- and post any game enriched intervention. This allows for a much stronger analysis of the effects but also a deeper analysis and requirements for the KCCC outpatient department. In this paper, we demonstrate how functional neuroimaging analysis of these dense EEG measurements can reveal brain sources/areas responsible for the de-noising of the elderly brain after the intervention. What is more, functional connectivity network analysis can reveal a reorganisation of the default mode network due to combined physical and cognitive training. Our results refer to a wide pilot deployment involving more than 150 senior subjects over an intensive training protocol of 2 months.

Besides this, recent emergence of motion capture technology has enabled acceptable unobtrusiveness as well as other features of making the game challenging and seniors being motivated. A key
step towards this direction would require using emotional queues in the midst of the game-flow and within the gaming environment, so as to allow for suitable embodiment of real-time mental (cognitive and emotional), and physical data. To properly study the above, one needs ecologically valid but yet controlled set-up, in the form of home-like environments. We have designed and implemented such an Active and Healthy Aging Living Lab/e-home within our Assistive Technologies and Silver Science Lab to facilitate such simulation as well as experiments and recordings with real elderly users. A vast amount of “daily-living” data is therefore created. These are then analysed with intelligent methods enabling early symptom identification and allowing decision support for early disease diagnosis. Emphasis is given on interlinking robust scientific methods and tools of studying emotions, as well as, age-related cognitive decline within the gaming environment and in-game metrics.

SP113.7 - Intelligent System for Identification of patients in Healthcare

Author(s): Alexandra Vasquez1, Monica Huerta1, Roger Clotet1, Ricardo Gonzalez2, Giovanni Saqby2, David Rivas3, Jose Pirrone Puma4

1Networks And Applied Telematics Group, Universidad Simon Bolivar, Caracas/VENEZUELA, 2Electrónica, Universidad Politécnica Salesiana, cuenca/ECUADOR, 3Electronic, Universidad de las Fuerzas Armadas, Latacunga/ECUADOR, 4Esc. Ingenieria En Telecomunicaciones, Universidad Catolica Andres Bello (UCAB), Caracas/VENEZUELA

The Inadequate identification of patients in health care centers remains as a common problem that has brought incidents and adverse event to this kind of facilities. This work present a system design to deal with this situation. To develop this proposal different identification systems and patient monitoring systems in health centers was studied, and a comparative study was conducted between existing technologies to develop this proposal. The NFC technology was chosen to develop a system solution because of its availability in mobile phones, its feature of information security, speed, low cost and simplicity in data exchange. Confidentiality of the patient information is guaranteed through authentication profiles for system access and data security through SSL and HTTPS protocols. The purpose of the proposed system is to provide correct information transfer, keeping track on patients and facilitate control of them by the health care center staff, in order to minimize accidents and mistakes of identification and to improve the healthcare facilities’ quality.

SP114 - Dosimetry and Radiation Protection

SP114.1 - Development of Object Simulator for Evaluation Periapical Radiographs

Author(s): Jadna M.S. Mendes1, Elias S. Sales Junior2, Cinthia M.M. Paschoal3, Cledison J. Cunha4, Lourdes M. Brasil4, Fernanda C.L. Ferreira1

1Federal University of South and Southeast of Pará, Marabá/BRAZIL, 2Physics, Federal University of South and Southeast of Pará, Marabá/BRAZIL, 3Civil Engineering, State University of Vale do Acaráu, Sobral/BRAZIL, 4Physics, Federal University of Sergipe, São Cristovão/BRAZIL, 5University of Brasilia, Brasilia/BRAZIL

This study aimed to develop a dental phantom with cysts for evaluation of periapical radiographs that was tested in private dental offices in the city of Maraba, northern Brazil. Through some tests with the object simulator (phantom) were obtained 12 periapical radiographs (one in each of the offices visited) that waking up to the standards of Ordinance N. 453 were visually evaluated by observing the physical parameters of exposure (kVp and mA), time, and the quality of radiographic film, later the other radiographs were visually compared with C6 ray set as the default. Among the results, it was found that only two of the twelve rays cysts could not be viewed and, therefore, these two images were deemed unsuitable for accurate diagnosis in the 10 images the cysts could be displayed, however according the images have different qualities comparisons. In addition, it can be concluded that the performance of the phantom was highly satisfactory showing to be efficient for use in quality control testing of dental X-rays, the quality control of radiographs and continuing education of dental professionals for a price much more accessible.

SP114.2 - Impact Created by Medical Physicist from Regulatory Quality Assurance Controls in Developing Country

Author(s): Samba Richard Ndi1, Simo Augustin2

1Control And Inspection, National Radiation Protection Agency, Yaounde/CAMEROON, 2Directorat General, National Radiation Protection Agency, Yaounde/CAMEROON

Background: The use of Ionizing Radiation in medicine has been increasing rapidly over the years in Countries in general and Cameroon in particular. Individual occupational exposure and patient safety varies widely among those involved in medical care. There are certain medical procedures that might give substantial doses to medical staff, normal tissues of patients and the education of medical professionals in radiation protection and quality control issues are continuing problems. Regulatory bodies are mandated through laws and regulations to regulate all ionizing radiation sources as well as the protection of people and environment against ionizing radiation hazards.

Objectives: Improvement of regulatory framework by Medical Physics Quality Assurance Controls.

Methodology: National Radiation Protection Agency (NRPA) of Cameroon activities started with inventory program in 2009, which was completed in July 2010. Over 500 occupationally exposed workers were recorded with about 12 % being monitored 5% of quality assurance undertaken. There was no national dosimetry service provider, all were monitored from abroad. Regulatory Technical control started in 2011. A medical physicist was employed by NRPA in 2010 to coordinate Quality Control and dosimetry activities as
ABSTRACTS | IUPESM 2015 WORLD CONGRESS ON MEDICAL PHYSICS & BIOMEDICAL ENGINEERING

regulatory aspect. There were a lot of discrepancies recorded at the level of occupational monitoring and state of equipment to produce quality images. NRPA acquired dosimetric monitoring and quality control kits in 2010 and 2011 respectively. These are widely used in quality control, radiation protection and safety, offer a number of potential advantages for medical applications (diagnostic and radiation therapy).

Results: As of 2014, remarkable improvement has been noticed in the dose reduction of workers, patients and the quality of the machines used in then controlled medical facilities. In this, the results of occupational exposure from 2011 to 2014 is shown and the results of the quality control executed from 2011 and 2014 compared are illustrated in tables.

Recommendation: Recommendations are ditched out to competent authorities at various levels for the continuous improvement of quality assurance programme and occupational monitoring to safeguards radiation protection/safety culture.

Conclusions: Radiation Principles are being applied by using national and international standards for the benefits of both patients and workers in radiological practices. This can never be sustainable without the creation of the awareness of Medical Physicist policy and roles in developing countries.

SP114.3 - Evaluation of Dental X-rays equipment in Sobral-CE, Brazil

Author(s): F L. Meneses1, Fernanda C.L. Ferreira2, Cinthia M.M. Paschoal1

The ionizing radiation has important application in dental diagnosis. In Brazil, the National Ordinance No. 453/1998 of the Ministry of Health regulates the operation of medical and odontological diagnostic radiology services. However, the inspection of periapical dental X-ray equipment is not carried out by some Sanitary Surveillance. This study intended to determine the suitability to the ordinance of the dental offices of Sobral-CE, Northeast of Brazil, and to compare the results with literature data for other cities of Brazil. It was performed tests of radiation field and image quality, and it was applied questionnaires to the professionals. For the image quality test, it was used a dental phantom and the processing of the films was performed in the clinics and at the laboratory (standard). The questionnaire assessed physical parameters that interfere on the radiation protection and on the quality of images. The results show that the ordinance is not being properly followed and that it is necessary to inspect the periapical X-ray equipments. Moreover, in general, it is observed that dental professionals should have better training on ionizing radiation and on radiation protection.

SP114.4 - Effect of static magnetic field exposure on human blood electrolyte levels in vitro

This proposed paper presents a study of effect of strong static magnetic field (SMF) exposure on electrolytes in human blood in-vitro. There have been major concerns of safety from magnetic fields (static and dynamic magnetic fields) to life and their effects on physiology. It is noteworthy that magnetic fields are listed as ‘Potentially carcinogenic’ by W.H.O. There are evidences of SMF causing special sensations in humans and animals like bizarre behavior and magnetophosphenes, these are probably attributed to cell membrane property changes.

Magnetic therapy is a treatment modality being used since ages, the claimed mechanism of action being the presence of iron in the blood and the alteration in blood viscosity, which is mostly doubted by the modern science.

Here, the effect of SMF exposure on blood electrolytes was studied. A Case - Control study was carried out, collecting blood samples from healthy young volunteers. The samples were divided into 6 equal parts in 3 pairs of Case and Control, and exposed in vitro for 20 minutes to SMF strengths of 500 Gauss (G), 5000 Gauss and 1 Tesla respectively one after the other. Here case sample was exposed to 500G SMF generated by a coil electromagnet between 2 soft iron cores and the control samples shielded by placing in an iron box. After 20 minutes of exposure and shielding, both samples were estimated for electrolytes: K+, Ca++, Na+, CI and pH by indirect Ion Selective Electrodes method on a Combiline® blood gas analyzer machine. The process was repeated for the other pairs of samples with cases on 5000G and 1 Tesla (1 Tesla = 10000 Gauss) SMF one after the other and shielding controls to match the effects of the time lapse. The data acquired was analyzed by applying paired T test on the case and control samples for each ion parameter at each SMF strengths exposed, the P value was taken to be significant at p<0.05. Here, no statistically significant changes in the ion concentrations of the case and control samples were found. The results indicate that the SMF of 500 Gauss, 5000 Gauss and 1 Tesla did not result in any significant change in the electrolyte concentration in the samples, possibly inferring to no significant change in leakiness of the red blood cell (RBC) membrane.

This study suggests that very strong SMF of up to 1 Tesla, as used in this experiment, do not affect the electrolytes and possibly the leakiness of the RBC membrane in vitro. In this study it was also found that the SMF of around 500 Gauss, the strength of the magneto-therapy magnets also did not show any change in electrolyte concentration, hence no change in membrane leakiness of the RBCs. This study, hence points towards the safety of the magnetic field exposure on the red blood cell membrane leakiness.
SP115 - CT Image Quality and Dose Optimization

SP115.1 - Towards Image Quality Analysis of Small and Full Field of View Dental Cone Beam CT Systems

Cone-beam CT (CBCT) systems have been used for dentomaxillofacial surgery applications. Different dental CBCT devices are being developed and released, with a wide variability of exposure parameters and fields of view. Although they have sufficient diagnostic quality, a quantitative analysis of image quality and radiation dose is required to enable their optimal use. The aim of this study was to develop and implement a feasible methodology for image quality analysis for different dental CBCT devices. The methodology was based on conventional CT quality control procedures and adapted to overcome the limitations of dental CBCT. A prototype phantom was specially designed to allow the acquisition of image quality parameters relevant to dental imaging. Equipments were divided into categories, related to their field of view: Small Field of View (SFOV) and Full Field of View (FFOV). The following image quality parameters were evaluated: uniformity, noise, contrast-to-noise ratio, CT number accuracy, artifacts, spatial resolution and geometric distortion. Applicability of the methodology was assessed using one SFOV and four FFOV CBCT devices. Results from preliminary analyses of the prototype phantom showed its potential for routine quality assurance on dental CBCT. Large differences in image quality performance were seen between the devices.

SP115.2 - Rapid non-invasive spatially varying HVL measurements for CT sources

Author(s): Matthew Randazzo, Mauro Tambasco
Physics, San Diego State, San Diego/CA/UNITED STATES OF AMERICA

Purpose: A method is presented to generate spatially varying half value layers (HVLs) that can be used to construct of computed tomography (CT) x-ray source models for CT dose computations.

Methods: To measure the spatially varying HVLs, we combined a cylindrical HVL measurement technique with the characterization of bowtie filter relative attenuation (COBRA) geometry. An apparatus (HVL-Jig) was fabricated to position a real-time dosimeter off-isocenter while surrounded by concentric cylindrical aluminum filters (CAFs). Data was acquired using axial CT protocols filters to investigate the energies of 80, 100, and 120 kVp on a single CT scanner (GE Optima CT580). In this geometry, each projection of the rotating x-ray tube is filtered by an identical amount of high-purity aluminum while the stationary detector records an air kerma rate versus time waveform. The CAFs were progressively nested to acquire exposure data at increasing filtrations to calculate the HVL. Using dose waveforms and scanner geometry, each timestamp was related to its corresponding fan angle. These measurements were validated against the more laborious conventional step-and-shoot approach.

Results: At each energy, HVL data from the COBRA-cylinder technique was fit to a trendline and compared with the conventional approach. The average relative difference in HVL between the two techniques was 1.3%. A systematic overestimation in HVL was observed due to scatter contamination, but by applying a 1% downward shift to all measurements, all differences lie within a 0.2 mm Al threshold needed to generate spectra for accurate Monte Carlo CT dose computations.

Conclusion: The rapid, accurate, and non-invasive approach described allows one to acquire the spatially varying fluence and HVL data using a single experimental setup and three scans. These measurements can be used to characterize the CT beam fluence and energy spectra along the BT filter direction, which can serve as input for CT dose computations.
SP115.4 - Evaluation of automatic exposure control systems in computed tomography

Author(s): Paulo R. Costa, Thamiris R. Reina, Denise Y. Nersissian
Nuclear Physics, Radiation Dosimetry and Medical Physics Group, Physics Institute, São Paulo/BRAZIL

Introduction: The greatest and relatively new advance in CT to lower the patient dose is the automatic exposure control (AEC) systems [1]. These systems modulate the dose distribution along the patient taking into account their size and tissue densities [2]. AEC-systems are complex and their functioning is not fully understood [3]. This work aims to evaluate the performance and susceptibilities of AEC-systems.

Methods: The approach was the extraction of tube current modulation (TCM) data from DICOM image sequences and analysis of the image noise of those images [4]. The TCM of each CT scanner provides the performance of the AEC-system. Dose measurements with the AEC-system ON and OFF were made to verify if the tube current was consistent regarding the dose distribution behavior.

Results and Discussion: Figure 1 shows the TCM, and the corresponding noise for a Philips Brilliance 16 longitudinal AEC mode, Z-DOM, and the longitudinal AEC mode with the DoseRight ACS option ON. This example shows that this option causes a great increase on tube current, with a lower image noise and it doubles the dose compared to Z-DOM with this option OFF and the image noise decreases about 25%.

Conclusions: The results attained give rise to optimizations on the AEC-systems applications and, by consequence, decreases the patient dose without compromising the diagnostic image quality.

Acknowledgments: The authors thank FAPESP (project 2010/12237-7) and CNPq/FAPESP INCT Radiation Metrology in Medicine.
SP115.5 - Development of a Software for Image Quality Assessment in Computed Tomography using the Catphan500® Phantom
